THIS authoritative work has now reached its conclusion. The present volume, which is the fourth of the translation, contains an account of the development of the Amphineura, the Lamellibranchiata, Solenoconcha, Gastropoda, Cephalopoda, Tunicata, and Cephalochorda. The descriptions given in the text of the successive stages of development in these groups are exhaustive up to the year 1893. Since that period considerable additions have been made to our knowledge by the labours of many naturalists, with the result that it has become necessary to supplement the statements made by Professor Korschelt and Professor Heider by the introduction of footnotes. These have been very judiciously added by Mr. Martin F. Woodward, and in some instances fill up lacunæ which existed when the origina was written; in other instances they modify the results that had then been obtained; and in others again substitute new and more correct accounts derived from the concordant researches of more recent investigators for the older and less accurate observations. Mr. Woodward has greatly added to the value of the translation by appending to the excellent bibliography given by the authors a list of the more important articles that have been written since the date of publication of the German work. Thus, in addition to the 113 articles on the Tunicata supplied by Professor Korschelt and Professor Heider in the bibliography of that order, Mr. Woodward adds no less than 37 references to important articles and treatises that have appeared in the course of the last seven years. The student, therefore, will have but little trouble in following up certain lines of inquiry and completing his knowledge of all that has been done up to the end of the last century.

The general mode of treatment of the subject of embryology adopted by the authors may best be understood by selecting one of the orders, such, for example, as the Gastropoda. In dealing with this order Professor Korschelt, by whom the description appears to have been chiefly written, discusses in succession the oviposition and character of the egg-capsules and the egg, in which it is shown how in most Gastropoda the spawn forms disc-shaped or long hyaline gelatinous masses sometimes inclosing several hundred thousand eggs which are fertilised in the body of the

mother; in others the ova are laid singly and are fertilised in the water. To this succeeds an account of the cleavage and the formation of the germ layers; then the rise of the larva and its relation to the adult form, including the trochophore and veliger stage in Patella and the corresponding stages in Paludina; then follows a description of the primitive kidneys. The development of the external form of the body in the different divisions of the Gastropoda, as in the prosobranchia, opisthobranchia, pteropoda, &c., is given with the formation of the various organs, as the shell, nervous system, sensory organs, pedal glands, alimentary, respiratory, circulatory, and generative systems. It will be seen from the above *résumé* that the account of the development of this order is very complete, and the same may be said of the lamellibranchia, cephalopoda, and other divisions of the great class of mollusca. Nothing can show better the immense extension of our knowledge of the subject of development of late years than a comparison of the space occupied in Balfour's well-known Comparative Embryology, published in 1880, as compared with that in Professor Korschelt and Professor Heider. In the former work the consideration of the embryology of the mollusca only occupied 55 pages, whilst in the latter it takes up nearly 600 pages. There is, however, still room for further investigations. To give an example only, are the so-called arms or brachia of the cuttle-fish processes of the foot, as Professor Huxley believed, or are they, as Grenacher held, representatives of the velum, the foot being absent in this group? The question still remains unanswered, though the evidence seems to point, upon the whole, to the correctness of the view held by Professor Huxley. Professor Korschelt, in admitting this, remarks that a fact which causes surprise and at first sight is unfavourable to it is that some of the arms shift to the dorsal side of the head, being here found behind the mouth. "This makes it difficult to understand how the foot could have become transformed in this way, but when we see how extremely plastic it is, judging from different transformations it has undergone in the Lamellibranchia, the Prosobranchia, the Heteropoda, and the Pteropoda, further modification is not so inconceivable, especially when we find that the lateral parts of the foot in certain Prosobranchia (diotocardia) even develop tentacular structures."

The lady, Matilda Bernard, whose name appears on the title-page as the translator, deserves great credit for the care and fidelity with which she has rendered the original into pure and idiomatic English. We have opened the volume in many places and compared the translation with the original and in no instance have we found any slovenly expression or any incorrect rendering of the German. The illustrations are not only very numerous but extremely good, while the general get-up of the volume in regard to paper and print renders it very pleasant to read.

A Text-book of Practical Medicine. By WILLIAM GILMAN THOMPSON, M.D., Professor of Medicine in the Cornell University Medical College, New York City; Physician to the Presbyterian and Bellevue Hospitals, New York. Illustrated with 79 Engravings. London: Henry Kimpton. 1900. Pp. 1011. Price 21*s*.

THE author of this work states in his preface that his aim has been to offer to students and practitioners a comprehensive review of up-to-date medical practice. He has made a special effort to set forth clearly and simply those facts and principles which have received clinical proof and to avoid those theories which have merely a speculative basis. We consider that Dr. Thompson has carried out his objects. One of the features which distinguish this text-book from those hitherto published is the care with which the treatment of the various diseases is described. This is evident throughout the volume. Curative medicine is assumed to be the final and avowed object of those who may read this work, and the therapeutical sections have therefore been made unusually detailed and complete.

The book is divided into nine parts. Part I. deals with Infectious Diseases. It is instructive to note how with the publication of new text-books of medicine, or with the issue of fresh editions of older ones, the section concerned with "infectious diseases" is gradually getting larger and larger as our knowledge of bacteriology increases. In this volume pneumonia, rheumatism, tuberculosis, and gonorrhœal arthritis are all included. Probably some of the "diseases of the blood" will ultimately find their way under the same heading. The chapter describing Typhoid Fever is a very good one, especially that part dealing with the treatment. The author especially advocates hydrotherapy according to the method advocated by Brand—that is to say, the application of friction to the entire body while immersed in the cold water. In this country the use of the cold bath in the treatment of typhoid fever is very extensively employed, but the "rubbing" is not so generally used. Dr. Thompson, however, lays great stress on the importance of this measure and considers that Brand's method would be more appropriately termed treatment by "rubbing" than by "tubbing." The object of the friction is primarily to apply a mechanical stimulus to the cutaneous surface over a large area, thereby reflexly stimulating the entire nervous system and also the vaso-dilator nerves of the periphery, which allow of the determination of increased supply of blood to the surface to be cooled by the water. Dr. Thompson has had most satisfactory results by employing this system of treatment.

The account given of malaria is very full and complete. The varieties of malarial parasites are accurately described and the symptoms of the different types of malarial feve clearly recounted. Dr. Thompson considers that quinine in the treatment of malaria furnishes the best illustration of the action of a true specific remedy known to therapeutics and he is inclined to agree with the statement made by many recent writers that fevers which do not yield to it are not malarial. He further states that in no case of malaria is it desirable to give quinine during the height of the fever, for it may not be then absorbed and is often vomited.

The author defines pneumonia as "an acute, infectious, febrile disease, caused by inflammation of the lungs, with toxæmia." This is scarcely accurate; pneumonia is now regarded as an acute, infectious, febrile disease with local manifestations in the lungs, but the pulmonary process is not strictly an inflammation, and the disease is certainly not "caused by inflammation of the lung," but by a micro-organism. The clinical description of the disease, however, and the treatment are well given. In speaking of the latter the author describes some experiments he made to determine the penetrating power of local heat and cold; this was in reference to the local measures of treatment sometimes adopted in pneumonia—by hot poultices or the application of ice. Specially constructed thermometers inserted deep into the chest through empyema sinuses were unaffected by external poultices or ice-bags. Experiments on dogs showed no change in the lung, neither congestion nor anæmia, when similar applications were applied to the chest wall.

We particularly commend the remarks on the examination of the contents of the stomach in cases of gastric disease. In recent years there has been a tendency to trust too much to the results of such chemical analysis to the exclusion of clinical observation. Dr. Thompson points out very justly that analyses of gastric contents are merely of corroborative value in connexion with a comprehensive study of each case, including the history, physical examination, and general symptoms, and he adds, "attempts to isolate them for

positive conclusions as to diagnose or indications for treatment will result in grave error." We cordially agree with the author's remarks.

Comparative tables are freely used as an aid to differential diagnosis; this affords a ready and great assistance for reference. The busy practitioner can see at a glance the main points that are relied upon in distinguishing from one another those diseases which bear mutual resemblances.

There is one matter in which we entirely disagree with the author in his classification of diseases. He has set down "jaundice," "dilatation of the heart," "dilatation of the stomach," "ascites," &c., as though they were distinct diseases instead of symptoms or the results of diseases. We admit that this arrangement is convenient for teaching purposes, but the student is always too apt to regard these conditions as primary disorders and to forget to search for their true origin.

Report on an Experimental Investigation into Methods of Inoculation against Rinderpest. By LEONARD ROGERS, M.D., B.S. Lond., F.R.C.S. Eng., officiating Imperial Bacteriologist to the Indian Government.

THE Government of India have recently issued a report on the above subject showing the results of some most valuable and painstaking observations which have been made by Captain Rogers of the Indian Medical Service and his veterinary assistant Lieutenant Walker, A.V.D The objects of the investigation were to test different methods of inoculation recently adopted so successfully in South Africa when dealing with rinderpest outbreaks, and to report upon the prospects of practically applying similar measures in India. Captain Rogers has entered into the subject most exhaustively and has given extensive trial to inoculation with Koch's bile, Edington's glycerine bile, filtered bile, serum alone, Turner and Kolle's method, and the serum re-inoculation method. The advantages and disadvantages of each are fully discussed and the author's conclusion set out to the following effect. With Koch's bile method the principal advantages are that only a single inoculation is required, and there is no reactionary fever which would be likely to produce loss of milk in dairy cattle or abortion in pregnant animals. The principal disadvantages are, first, the difficulty of obtaining suitable biles in sufficient numbers in village outbreaks, and, secondly, the short duration of the immunity. In connexion with the latter it is curious to note that in the case of hill cattle the immunity produced did not last even for a month in many instances. Again, complete immunity is not obtained for ten days after the inoculation, and during this time the whole herd may have contracted rinderpest in a fatal form. Edington's glycerine bile method gives an immunity of long duration, and the biles can be kept in a condition in which they can be used for upwards of a year. On the other hand, full immunity is not obtained for at least ten days, infection is introduced by this method, and a double inoculation is necessary, the latter procedure requiring the collection of all the animals a second time. With this method a large proportion of the cattle on the plains failed to react, whilst in the hill animals it was not only useless but almost always fatal. With the filtered bile method a week's time is gained over Edington's method and biles which have become putrid can be utilised. This is also dangerous to the hill cattle. The use of serum alone affords immediate and full immunity, and will modify an attack of the disease which an animal may have contracted one or two days before its use. The serum can be prepared in any quantity and is well spoken of by the author. To Turner and Kolle's method the most serious objection is that it is useless in the Kumaon hill cattle, as in these very susceptible animals the results obtained were erratic. The serum re-inoculation method consists in using a sufficiently large dose of serum on one side of the animal to counteract a small dose of rinderpest blood injected on the other side at the same time. It gives a mild and safe reaction, so that even hill animals can be passed through a mild attack of rinderpest with little, if any, loss. The only disadvantage, a minor one, is that a second inoculation is necessary in some of the animals. In conclusion, Captain Rogers states: "While, then, the re-inoculation method presents decided advantages in this country, it must be left to further experience in the field to decide whether this advantage is sufficiently great to overcome the greater trouble that it involves in the case of plains animals; but, on the other hand, in the case of hill cattle it alone gives good and safe results. ..... In the event of sufficient serum for carrying out these methods not being at any time readily available then the glycerine and filtered bile methods will be of the greatest value."

Verhandlungen des Congresses für Innere Medicin. (*Proceedings of the Congress on Internal Medicine.*) Edited by Dr. E. VON LEYDEN and Dr. EMIL PFEIFFER. Wiesbaden: Verlag von J. F. Bergmann. 1900. Pp. 638.

THIS volume contains an account of the eighteenth congress on Internal Medicine held at Wiesbaden from April 18th to 21st, 1900, of which we gave a report in THE LANCET at the time.

The opening address by Professor Dr. Rudolf von Jaksch is reported in full, the title being "Internal Medicine in the Nineteenth Century and its Probable Development in the Twentieth Century." An important discussion took place on the treatment of pneumonia, being introduced by Professor D. Friedrich von Korargi (Budapest) and Professor Dr. P. K. Pel (Amsterdam). A large number of speakers subsequently expressed their views on the subject, including Professor Nothnagel of Vienna, Professor Senator of Berlin, and Professor Baümler of Freiburg. Another interesting discussion was that on Endocarditis and its Relations to Other Diseases, introduced by Professor Litten of Berlin, and amongst the speakers were Professor von Jürgensen of Tübingen and Professor His of Leipsic.

A large number of communications were read, some of them being of considerable interest—such us: the Gouty Affections of the Stomach and Intestine, by Dr. Karl Grube of Neuenahr and London; the Pathology of Paroxysmal Tachycardia, by Dr. August Hoffmann of Dusseldorf; on Cyanosis, by Professor Hermann Vierordt of Tübingen; and on Phlorhizin-Diabetes, by Professor Arthur Biedl of Vienna and Dr. Rudolf Kolisch of Vienna. There are upwards of 40 papers published. These, with descriptions of certain clinical demonstrations, form a valuable collection and the writers may be congratulated on having published a volume which is likely to prove of considerable value, especially for purposes of reference.

Diseases of the Heart: Their Diagnosis and Treatment. By ALBERT ABRAMS, A.M., M.D. Heidelberg, Consulting Physician for Diseases of the Chest, Mount Zion Hospital, and the French Hospital, San Francisco. Chicago: G. P. Engelhard and Co. Pp. 178. Price $1.

THIS book will have to undergo a considerable amount of revision and alteration before it can be considered a reliable work on diseases of the heart. At present it is full of inaccuracies and expressions of opinion which are far behind the times and which have long been disproved by the most competent observers. A few illustrations will suffice. In speaking of ascites the author says: "The chief cause of cardiac dropsy is disease of the mitral valve, and especially *mitral stenosis*" (the italics are quoted). Again, in the section on Dilatation of the Heart we find the remarkable statement

"Dilatation of the heart is an evidence of weakness of the organ and it usually follows hypertrophy." This is misleading, for although dilatation may certainly ensue in a heart which is hypertrophied, in the majority of cases dilatation precedes hypertrophy. In describing endocarditis Dr. Abrams writes: "The malignant form is of microbic origin and is secondary to some infectious disease. The majority of cases develop during an attack of croupous pneumonia." We differ from both these statements. Primary infective endocarditis does undoubtedly occur, and the most common form of micro-organisms found in relation with this condition belong to the septic and pyogenetic type (streptococci and staphylococci).

Dr. Abrams has also some original ideas on methods of diagnosis. He uses the x rays to diagnose a dilated stomach, and by the same means has actually discovered that dilatation of the right heart follows severe muscular exertion, such as "century runs"! The author should make himself acquainted with the safety-valve action of the tricuspid valve before enunciating as a new fact a condition which is known to every senior medical student. Dr. Abrams is evidently much impressed with the value of the Roentgen rays. We do not think the following sentiment will be generally accepted: "The vast amount of literature that has ..... accumulated has convinced the most skeptical that the Roentgen rays are invaluable in cardiac diagnosis"; or that his concluding remark on this subject will generally commend itself: "Without a Roentgen ray apparatus no physician can lay claims to scientific refinement in cardiac diagnosis."

We could multiply criticisms similar to the above, but we have already allotted sufficient space to a publication which we cannot in any way recommend.

A Practical Guide to Garden Plants. By JOHN WEATHERS, F.R.H.S., late Assistant Secretary to the Royal Horticultural Society, Horticultural Lecturer to the Middlesex County Council, &c. London: Longmans, Green, and Co. 1901. Pp. xii.-1192. Price 21*s.* net.

THE chief aim of Mr. Weathers in writing this work "has been to produce a book that will be unique and of real use, not only to amateur gardeners, for whom it is particularly intended, but also to those engaged professionally in horticulture." The arrangement of the volume is very good. The first portion consists of a glossary in which are defined the various technical words, &c., used in descriptive botany. The explanations given are both numerous and concise; also illustrations are freely used, so that the exact meaning of any particular term can hardly be misunderstood. The presence of a glossary must not, however, be taken as indicative of the occurrence of plant descriptions bristling with technical expressions. We are pleased to note that it would hardly be possible to describe plants in simpler language.

Part I. deals with the life-histories of cultivated plants; it contains much information concerning the nature of plants from many points of view. For instance, structure, morphology, and some physiological processes are briefly entered into. Propagation is very clearly and fully described, and, where necessary, illustrated. A few errors may be found in the earlier portions of this section. For example, on page 25 occurs the following statement:—"It (the embryo) may occupy only a very small space as in wheat, onion, &c., and remain imbedded in a substance at one time called '*albumen*,' but now more generally called '*perisperm*.'" It is hardly necessary to point out that it is the endosperm which is synonymous with the albumen, and of course endosperm and perisperm are two quite different tissues, which, however, fulfil the same functions. Then, again, the language is sometimes rather loose, thus making some of the statements open to misconception. For instance, on page 30 we read, "It is evident, therefore, that the sap from the roots ascends by the vessels in the cambium and young wood." The presence of vessels in a cambium would indeed be remarkable.

Part II. occupies by far the greater portion of the book. It enters into the consideration of annual, biennial, and perennial plants. Lists, which will prove of great use, are given of annuals, rock-plants, aquatic plants, and ornamental trees, together with general directions as to their culture and arrangement. As regards the arrangement of plants we notice that in some special cases—e.g., rock-gardens and flower-borders—articles published elsewhere are made use of. The one relating to the "Formation of a Rock-garden" is particularly instructive. The last section of Part II. gives descriptions, mode of culture, and other information of a very large number of plants, in fact, over 1000 genera are mentioned.

Parts III. and IV. are concerned with the cultivation of fruits and vegetables respectively.

In conclusion, the work is extremely good and contains all necessary information for the cultivation of plants. To amateurs it will prove invaluable.

LIBRARY TABLE.

Laboratory Directions for Beginners in Bacteriology. By VERANUS A. MOORE, B.S., M.D. Boston: Ginn and Co. London: Edward Arnold. 1900. Pp. 143. Price 4*s.* 6*d.*—This book consists of a series of exercises or bacteriological experiments for beginners. Step by step the student gradually makes his acquaintance with applied bacteriology and his attention is drawn to the great importance of bacteriological examination as a means of diagnosis. His first exercise is directed to the cleaning of glassware, his second to the plugging of tubes and flasks and to the sterilising of glassware, his third to the preparation of culture media. In all there are 64 exercises, in the course of which the search for pathogenic organisms in tissues, in water, and in excretions is described. The exercises include the testing of the efficiency of disinfectants. We regard the work as an excellent guide for the study of practical bacteriology and we know no better method of inculcating practical bacteriological knowledge than by setting a pupil a series of exercises on the plan and in the order given in this valuable little work.

An Introduction to Modern Scientific Chemistry. By Dr. LASSAR-COHN, Professor in the University of Königsberg. Translated from the second German edition by M. M. PATTERSON MUIR, M.A., Fellow of Gonville and Caius College, Cambridge. London: H. Grevel and Co. 1901. Pp. 356. Price 6*s.*—Concerning the title of this book, what is chemistry if it is not scientific? The superfluous adjective is used, perhaps, because the present book is written in the form of popular lectures, and thus a kind of apology for putting the subject popularly is tendered in the word "scientific." Surely the science of chemistry is preserved even when it is expounded in popular language. Dr. Lassar-Cohn is the author of "Chemistry in Daily Life," which also was translated by Mr. Muir, and the present book is equally successful, we think, in regard to its presentation of chemical facts and principles in a popular style, although the work before us is more adapted than the previous one for the really earnest student of natural science. It should prove an excellent companion to a laboratory course of elementary chemistry. The book fulfils a distinctly educational purpose. A section is devoted to a consideration of the classification, composition, and constitution of carbon compounds.

Urinary Diagnosis and Treatment. By JOHN W. WAINWRIGHT, M.D. Chicago: G. B. Engelhart. 1900. Pp. 140. Price $1.—The author has extracted from the literature

on the subject the simplest methods of chemical and microscopical examination of urine and the latest theories concerning routine treatment of the conditions found. He has certainly reduced the analysis and examination of urine to the simplest possible form, and he gives, perhaps, for the busy practitioner sufficient information. But the omission of certain methods and the details of a few highly accurate, though perhaps complicated, processes may in some instances lead to the loss of a factor in diagnosis. At the end of the book is a series of excellent plates of urinary casts and crystalline deposits.

Appeal Cases under the Sale of Food and Drugs Acts, 1875 and 1879, and the Margarine Act, 1887. By B. SCOTT ELDER. London: Butterworth and Co., 12, Bell-yard. 1900. Pp. 90. Price 3*s.* net.—This book consists of a series of excerpts from various appeal cases under the Food and Drugs Acts, 1875 and 1879, and their selection has been undertaken by Mr. Elder, who is the chief inspector of food and drugs and weights and measures for the county of Durham. Of course, some of these appeals could hardly occur now under the new Act of 1899. The case in which baking-powder was held to be not an article of food is one in point, for baking-powder is now clearly included as an article of food in the new Act. The book will be consulted with advantage by those who are concerned in the institution of proceedings against presumable offenders.

The Food Inspector's Handbook. By FRANCIS VACHER, F.R.C.S. Edin., medical officer of health of Cheshire. Third edition. Illustrated. London: The Sanitary Publishing Co. 1900. Pp. 210. Price 3*s.* 6*d.*—This is a compilation of notes which should be very instructive to the food inspector and help him considerably towards the efficient discharge of his duties. An account of the food inspector's qualifications and obligations occurs in the first chapter, Mr. Vacher adding the attributes which should be possessed by the model inspector. The statutory powers are then discussed, while the practical side of the subject is approached in Chapter III. dealing with animals, carcasses, and butcher's meat, &c. We do not find any reference to a chemical means for identifying horseflesh. It would be interesting to know whether the iodine test depending upon the presence of glycogen was of any real value. Fish, fruit, vegetables, and fowl and preserved provisions form the subject of succeeding chapters. The final chapters deal with articles of food which for the most part come up for inspection and testing under the Sale of Food and Drugs Act. It appears to us that the food inspector will find in this little book all that he wants to know in connexion with the characteristics of various foods.

JOURNALS AND MAGAZINES.

New Zealand Medical Journal.—This periodical, which had for some time ceased to appear, was resuscitated in 1900. The first number of the new series was published in Wellington, New Zealand, in October; the second number, which is dated in November, consists of 50 pages and contains six original articles, the text of a proposed new Medical Practitioners Registration Bill, editorial paragraphs, and a variety of miscellaneous intelligence. In the opening article Mr. H. A. de Lautour of Dunedin describes his method of using the x rays for the localisation of foreign bodies embedded in the tissues. He wraps the sensitive plate in opaque paper and places it in a wooden box, the lid of which is crossed on the inside by several brass wires and on the outside is marked with lines corresponding to the wires. The brass wires are reproduced in the radiograph and serve to locate the exact centre. The box slides on a horizontal graduated steel scale attached to the base of the upright which carries the focus tube. When one radiograph has been taken the patient crosses over to the other side of the table and another radiograph is taken with a fresh plate. Tracings of each are then taken on one sheet of paper, always preserving the centre, so that double shadows of the foreign body are shown.

The *Journal of the Sanitary Institute*, which has just been issued, contains a long article by Professor A. Celli of Rome on Researches on the Propagation of Malaria and the Precautions to be adopted in Unhealthy Districts. After describing some of the opinions of other investigators he gives reasons for deciding that the dapple-winged gnat, known as anopheles, is the propagating agent. He then describes the life-history of the insect, and sets out a series of corollaries for the hydraulic engineer, for the sanitary engineer, and for the agriculturist, in which are detailed the steps that can be taken to prevent the multiplication of the anopheles and other measures against the spread of the disease. The concluding portion of the paper gives instructions for the self-protection of labourers in malarious places. The paper is illustrated by some of Professor Celli's photographs showing methods of protecting houses and shelters. The same journal contains papers of Dr. F. Tidswell, medical officer of health of Sydney, New South Wales, and Mr. S. M. Kaka, medical officer of health of Karachi, India, on their personal experiences of the plague in Sydney and Karachi, with descriptions of the preventive measures adopted. Some microscopic photographs of the plague bacilli and dissections of plague-infected rats and guinea-pigs appear in the paper.

Mercy and Truth.—The February number contains an illustrated description of the Church Missionary Society Medical Mission recently established in Riley-street, Bermondsey.

New Inventions.

HALL'S PATENT BATH APPLIANCE.

WE have received from Mr. T. Bernard Hall, 119, Colmore-row, Birmingham, a description and drawings of an appliance intended for use in asylums, infirmaries, hospitals, and similar institutions for the purpose of easily lowering and raising infirm, bed-ridden, and other invalids in and out of baths without distress to the patients or difficulty to the attendants. It can be fitted to any existing bath or supplied with new baths complete. The special feature of the appliance is a wooden grid or carrier on which the patient is laid and which is of a size and shape to suit the bottom of the bath. This grid is suspended by light galvanised wire or other ropes which pass over pulleys fixed directly above the bath, and are raised or lowered by turning a hand-winch provided with a worm and wheel and made fast to the wall in any convenient position. When a patient is to be bathed the grid is allowed to rest on two strips of wood laid across the bath, the patient is placed on it, the grid is slightly raised by turning the winch handle to allow the removal of the strips of wood, and the patient is then gently lowered into the bath. If the ropes are unhooked from the grid it may be used for carrying an invalid to bed or in connexion with an ambulance. The appliance does not in the least interfere with the ordinary use of the bath, as the grid may at any time be raised up out of the way. The invention is ingenious and might be useful in the houses of private patients as well as in the public institutions whose possible needs have been specially aimed at.

LUNACY IN BRISTOL.—At the meeting of the Bristol Board of Guardians held on Feb. 7th it was reported that on Jan. 1st, 1901, there were 1360 lunatics chargeable to the Bristol Union. Of this number 779 were in the Bristol asylum, 443 were in workhouses, 43 were in other institutions, and 95 were resident at their homes with relatives. The clerk stated that there was annually a steady increase in the figures.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 16, 1901.

The New Parliament and Domestic Legislation.

THE opening of any Parliament is always a matter of interest, but the ceremony of last Thursday was an event of exceptional importance to the nation. Parliament was opened by a new Sovereign accompanied by his Queen Consort with every circumstance of pomp and precedent that could give the ceremony weight, and in national circumstances which have commanded the attention of the world. Some of these circumstances have excited hostile criticism, as if England were now what Admiral COLLINGWOOD said she was a hundred years ago, "a target for all nations to shoot at"; but on the whole our relations with foreign States have been notably smooth since the death of the QUEEN moved all civilised nations to mourn her with us. The change of Sovereigns has evoked expressions of sympathy and respect which show that despite the different views of different races there is a substratum of reverence for what is good in all. We recognise the underlying humanity that has had its manifestation in the unprecedented recognition by all men of the virtues of QUEEN VICTORIA and in the generous sentiments which have been expressed towards her son who succeeds to her throne. The occasion is one of the greatest impressiveness, being the beginning of a new Parliament in a new century under a new ruler. The KING, the QUEEN, the Ministry, the Houses of Parliament, must feel that it is especially incumbent upon them to give the nation a new start in all that makes for the welfare of the people and for the peace of the world. His Majesty KING EDWARD VII. has given clear intimation that he realises the situation to which he is called and the duties of it. The British nation, subjects of QUEEN VICTORIA for 63 years, have conceptions of government and of Royalty such as no nation in the world have probably had before, and they look with confidence to the KING to rule them as they have been ruled, discipline being used to maintain and not to curtail freedom. Happy is the monarch who succeeds under such auspices.

KING EDWARD VII. steps on to the British throne at a time when there is a marked competition among the great nations for supremacy. The victory may or may not be ultimately settled by recourse to arms—God grant no such ordeal will be required at this period in the world's history; but military success and territorial aggrandisement are not the objects of national rivalry. What the peoples of the world seek are markets for trade. And the stress of competition in commerce between ourselves and powerful nations will not be without its advantages if it throws our statesmen back on the scientific use of the materials at hand. Long decades of wealth and luxury and prosperity have made us careless of efficiency. The new KING begins his reign with the discovery, nay, with the demonstration, that such conditions of life may be accompanied with much that is unhealthy, ignorant, and altogether unsatisfactory. The homes of many English people are hotbeds of disease and death. The education which is supplied to all gratuitously is inadequate for making life bright or for fitting the people for doing the best in their various callings. Dr. OLIVER LODGE, Principal of the University of Birmingham, said well to the members of the National Union of Elementary Teachers, in his address on "Educational Problems," delivered last week: "What scope for advance there is! Walking the streets how seldom one saw an educated face. How dull, uninterested, uncultured, and uninteresting the mass of mortals were." These are painful words, but as true as they are painful; and Parliament will be expected at the turning of a new page in history to endeavour strenuously to make of the wealthiest nation in the world the healthiest and the happiest. They may rest assured that in the KING they will have a well-informed and hearty coadjutor. It is to work with this object that Parliament is called as well as to the ending of the South African war in a victory of peace such as shall atone for its many horrors and failures. Lord SALISBURY and many lesser statesmen remind us in a somewhat vague formula that the great domestic problem before us is the provision of better houses for the working-classes. The Premier, in other words, perceives that the men who have to fight our battles must be healthy men with homes worth fighting for. The Colonial Secretary will heartily endorse this view, for is it not the fact that we owe to him one of the wisest Acts in our statute-book, though, alas, as yet little appreciated, by which for a sum not more than his rent the working-man may be helped by his municipality to buy in a reasonable time the house in which he lives. We could wish, indeed, that Mr. CHAMBERLAIN'S mind were liberated from its present cares to give help in the solution of those problems of sanitary, social, economic, and educational progress on which our ability to hold our high place among the nations clearly depends. But other members of Lord SALISBURY'S administration will be expected to see that legislation is undertaken to reduce the disease, the drunkenness, the ignorance, the incapacity of the nation. A Ministry that will not attempt such tasks cannot long retain the respect of the constituencies. Epidemics of disease over which science has given us complete control—control which has been tampered with by what is virtually the present Ministry—still threaten us; drunkenness still wastes the substance of the people and leads to the starvation of children and the wretchedness of homes; large numbers of people die without medical care or attendance; wealth monopolises space and land so that poverty in this vast metropolis can scarcely find a room in which decently to live. These are the evils in the remedies for which we are most immediately interested, and they are the evils which the British people, when their eyes are turned from South Africa to the motherland, will certainly insist upon having removed.

The South African war is an illustration of the way in

which an imperial question becomes a domestic one. In the memory of living persons the nation has not been moved to its heart more than by the various vicissitudes of this war. The bravery and brilliance of our soldiers have been largely neutralised and the reward of their militant virtues has been long delayed by defects of foresight, of organisation, of education—general, military, and scientific—which it must be the primary object and duty of statesmanship, rising above all party considerations, to supply. The British Empire is in need of statesmen of whom it can be said, as it was said of BURKE, "He saw everything and he foresaw everything." It is easy to be wise after the event. But we have a right to expect in our statesmen a more scientific forecast of things generally and a more intelligent study of the forces, social and political, which are moulding the nations, including our own, and which are bound to affect their action and their history.

Inoculation against Enteric Fever.

THE general results of a statistical comparison between the inoculated and uninoculated British soldiers serving in India, so far as an experimental trial has been made of Professor WRIGHT'S method of inoculating against enteric fever in that country, are stated to have been distinctly in favour of the inoculated. The results are, at any rate, sufficiently favourable to indicate that a further and more extended trial of this system of treatment should be made. An interesting communication from Professor WRIGHT published in THE LANCET of Feb. 9th, p. 399, furnished the results of an officially compiled statistical statement dealing with the effects of anti-typhoid inoculations in the case of one corps—the 15th Hussars. From this statement it appears that the incidence of enteric fever in the inoculated is represented as 0·55 per cent. and the mortality 0·27 per cent., while the incidence in the uninoculated is 6·14 per cent. and the death-rate 3·35 per cent. Although these figures are drawn from a comparatively limited number it will be seen that so far as they go they are very favourable to inoculation.

Inoculation against enteric fever has also been largely resorted to among the troops serving in the South African war, and the publication of the returns showing the results is anxiously awaited and should soon, we imagine, be forthcoming. The two sets of observations—those from India and those from South Africa—should furnish reliable data for estimating the influence of inoculation in lessening the soldier's liability to contract, or to die from, this form of fever, and it is quite possible that the returns from South Africa may turn out to be the more valuable of the two. According to official reports extending over many years it seems to be, statistically speaking, a well-established fact that the susceptibility of British troops under a short service system to contract enteric fever in India is most marked during their first and second years of service in that country, and notably during the first year. In the report of the Sanitary Commissioner with the Government of India for 1898, for example, we find that the ratio of mortality from enteric fever per 1000 of strength was greatest in the age-period 20–25. As regards residence in India, the ratio of mortality from enteric fever per 1000 of strength was highest in the first year of residence. The total number of deaths from enteric fever in the first year of Indian service was 236, and 70 out of every 100 deaths from all causes were from enteric fever. Out of the total number who died at all periods of residence from enteric fever 41 per cent. were in their first year of Indian service. These general results are, moreover, only confirmatory of those which have long been set forth in the official reports of former years. It may be pointed out, therefore, that any preponderance of soldiers in their first year's service on one side or the other—inoculated or uninoculated—might prove very misleading. The figures showing the results of inoculation might not be fairly representative of the advantages it confers where the subjects of inoculation were mainly composed of the class most susceptible of being attacked by enteric fever; on the other hand, the figures might unduly exaggerate the advantage where the least susceptible happened to form the majority of the inoculated class. It is highly probable, of course, that the troops serving in India have not been in any way specially selected, but have been taken, indiscriminately and as a mere matter of convenience, as they voluntarily offered themselves for inoculation; in which case there would be no such disparity between the inoculated and uninoculated as would practically affect the results of a comparison being made between them. The returns obtained from the troops serving in South Africa will not be open to any fallacy of this sort. The aggregate number of troops is very large; they are, or were, nearly all of about the same length of service in that country—that is, in their first year—and have all been subjected to the same or very similar conditions. The troops that came from India may, it is true, have already paid their tribute and have acquired immunity owing to their having been previously attacked with enteric fever whilst resident in that country, but the Indian contingents form no preponderating part of the army in South Africa. When all the figures bearing on inoculation against enteric fever and derived from observations made upon our army in South Africa are forthcoming we ought to have a good guide to th value of the treatment.

Supposing the protective influence of inoculation against enteric fever to be established as the result of these investigations, there still remain several points that will have to be determined before it can be generally applied as a practical measure—for example the degree of immunity which it confers and for what length of time it confers it. It need scarcely be said that the subject is not merely one of scientific or medical interest. It is devoutly to be wished that the evidence of figures and experiments, with which we have yet to be furnished, may prove sufficient to put the value of inoculation against enteric fever on a secure basis as a scientific and successful method of therapeutics. If this should turn out to be the case Professor WRIGHT will have conferred an inestimable boon not on the British army only but on humanity in general.

A Constant Water Service for London.

WE print in another column an account of the progress which has been made as to the provision of a constant water service for the inhabitants of London. The progress, it will be seen, has been slow, but it has been continuous. The advantages of a constant service were strongly insisted upon by Sir JOHN SIMON over 50 years ago, and statutory obligations of increasing stringency have been placed upon the metropolitan water companies as a result of the legislation of the years 1852, 1871, and 1897. At the present time every resident in London has a right to insist on receiving a constant supply of water from the company in whose area of distribution he lives, and should the company fail to carry out their duty in this respect they render themselves liable to pay a fine.

During the past few years some of the companies have failed to give a constant supply. These failures have been due to three chief causes:—

1. A company has had an inadequate amount of water at its disposal. More than one distressing famine has been suffered in the area of the East London Company from this cause. At length, happily, arrangements have been made by which the other companies can, when necessary, supply the deficiency by passing filtered water into the mains of the defaulting company. The Act passed to legalise this proceeding was the direct outcome of the first report of the Llandaff Commission.

2. A company has failed to give an adequate supply of water because it was deficient in regard to its means of purifying the river water. The Thames water is purified by means of sedimentation in reservoirs and afterwards by filtration.[1] The more completely the process of sedimentation is carried out the less the work the filters have to do and the longer they remain efficient. The early summer is the time at which the process of filtration causes most anxiety to the engineers of such companies as have an insufficient number of filter-beds. The surface of the sand is then liable to become blocked with a substance which is popularly called fish spawn. It will be remembered, at any rate by those who lived in the district, that some years ago a water famine in the area of the Lambeth Company was stated in Parliament to be due to the abnormal amount of fish spawn present in the river water which "choked" the filters. The fact unfortunately is that the reservoir capacity and the filtration area of the Lambeth Company are deficient, and so long as this is the case their customers will be liable to be the victims of such an accident.

3. Companies have failed to give a constant service because the water has during a severe winter frozen in the mains. This has occurred because the pipes have been placed too near the surface of the ground. Since the frost of 1894 many of the mains of the London companies have been relaid at a greater depth, but we are by no means convinced that they are all laid as they should be—that is to say, so deeply as to ensure that the water is in no danger of freezing.

It is essential for the well-being of the people of London that they should have a constant water service. When the companies have failed to give a constant supply it has been due to some fault or negligence on their part. They should not be allowed to profit by the faults which they have committed in the past, and the people of London should make them understand that future negligence, should it occur, will be punished in the manner provided for by the statutes. Where there is a constant water service domestic cisterns are not necessary if the mains are so laid as to obviate the effects of frost. It is always preferable to draw the water directly from the pipes. The metropolitan water companies are now trying to obtain the sanction of the Local Government Board to introduce some new regulations in regard to domestic fittings. They wish amongst other things to re-introduce cisterns into dwelling-houses. If the proposed regulations are adopted they will cause great expense and great inconvenience to the people of London. The water companies have skilfully chosen their time to carry out what, for them, would be a veritable *coup*. This is easily seen from the following facts:—

1. The President of the Local Government Board has only recently been appointed and cannot possibly have yet grasped all the difficulties of the question.
2. The Water Examiner to the Local Government Board has held office for a brief period only.
3. The London County Council have been unfortunate in their policy in regard to the water question generally, hence their opinion on this matter will probably receive less consideration than it should.
4. The new metropolitan borough representatives have not yet had time to study the question in detail.

We are strongly of opinion that the proposed new regulations should not be sanctioned by the President of the Local Government Board. The interests of the London water consumers have been unduly neglected. They are a long-suffering people, but should the President of the Local Government Board consent to the compulsory re-introduction of the domestic cistern we are moved to prophesy that the Government will alienate some of their best supporters.

[1] Except in the case of the East London Company which has no subsidence reservoirs at its Thames station.

Annotations.

"Ne quid nimis."

THE LANCET RELIEF FUND.

THE report of the Almoners of this Fund for the year 1900 is the twelfth in number, the Fund having come into operation upon Feb. 1st, 1889. The year 1900 showed, as might have been expected from the increase in the cost of living caused by the war, an increase in the number of applications and of grants. In 1899 the number of applications was 33 and the grants allotted numbered 24. In 1900 the applications numbered 42 and the grants allotted numbered 34. In 1899 there was only one grant which took the shape of a loan, all the others being definite gifts, while during the past year there were four loans and 30 gifts. The sums allotted varied from £5 to £20. It will be noticed that although the number of loans is still much less than that of the gifts, yet the loans for the year 1900 are more in number than the loans for 1899. We are rather glad to see the increase in the number of loans, for of the various cases which are presented for consideration there is none in which it is possible to extend a helping hand with a livelier sense of satisfaction than the case in which a timely loan helps a brother overtaken by adversity to help himself. But the form which the grant takes is no great matter. The chief thing to be considered is the advantage of the beneficiary,

and we as the benefactors can only hope that the grants from the Fund take that shape which is the most serviceable for those in whose interest they are bestowed. It is again our privilege to make public acknowledgment of the generous services rendered to this charity by the distinguished men who have associated themselves with it in the capacities of almoners and of auditor. We refer, of course, to Sir William Selby Church, Bart., the President of the Royal College of Physicians of London; Sir William Mac Cormac, President of the Royal College of Surgeons of England; Sir William Turner, the President of the General Medical Council; and Sir Henry Pitman, for many years the Registrar of the Royal College of Physicians of London. In presenting to each and all of them our thanks we assume to speak not only for ourselves as donors of the Fund, to whom its due administration is naturally a matter of solicitude, but in the name also of those who benefit by it and whose gratitude, not always articulate, is in not a few cases evidenced by expressions which it is a privilege to acknowledge but a satisfaction largely alloyed with sympathetic sorrow to receive. The application form of THE LANCET Relief Fund will be found in our present issue and can be readily detached for use in case of need. We again take an opportunity of asking those of our readers who may have occasion to assist in furthering any application made for relief from this source to note carefully the conditions on which applicants become entitled to participate in the benefits of the Fund, as it is still found that many requests are put forward which are so far outside the objects of the benefaction that they cannot be entertained and from such applications nothing but disappointment can result. All applications should be made on the prescribed form, and be sent to the Secretary of the Fund, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London.

MEDICAL CERTIFICATES AND THE LONDON SCHOOL BOARD.

AGAIN the old story of the relation of the London School Board to medical certificates has come to the front. On Jan. 30th a father was summoned by the board for not sending his child to school. There was no doubt as to the child's illness but the father did not hand in a medical certificate and therefore the magistrate disallowed the costs. This seems hard, but of course the father should either have procured a certificate or induced his medical attendant to give evidence. The question of payment, however, comes in. No medical man should be required to give a certificate without payment, but in many cases the parents are too poor to pay for one. Mr. Nelson Hardy, writing to the *Standard* of Feb. 5th, tells the following story illustrative of this point. He was in attendance upon one of the School Board teachers, and received a letter from a clerk who wrote to him stating that the medical officer of the board had asked him to write to Mr. Hardy to know if Mr. Hardy would be kind enough to let the medical officer have details of the teacher's illness. Mr. Hardy thereupon wrote to the clerk asking whether the board would pay a fee for professional information. Next came a letter from the medical officer himself, "telling me," says Mr. Hardy, "that it was the duty of a teacher to supply the board with full and complete information of any ailment from which he is suffering, and that he thought it only right, in the teacher's interest, that I, as his medical attendant, should have the opportunity of giving the opinion he (the medical officer) had asked for." Mr. Hardy's letter continues as follows: "Of course, I sent no opinion, but wrote instead asking the medical officer if he considered it ethically correct to ask a professional opinion from one of his medical brethren for which he knew that his board had no intention of paying, and also was he not well aware that the regulations requiring the teacher to supply the board with full information as to his ailments gave the practitioner to whom the medical officer applied no legal claim upon his patient for assisting the medical officer in the discharge of his duties. I have received an acknowledgment of this letter from the clerk but no reply to my queries from the medical officer." We do not quite see why the medical officer returned no answer and are sorry that he is not in a position to say that the usual fee, for instance the sum of 2*s.* 6*d.*, that was agreed upon by the board with regard to revised certificates, should be paid.[1]

THE ILLNESS OF H.R.H. THE DUKE OF CORNWALL AND YORK.

WE are authorised to make the following statement concerning the recent illness of H.R.H. the Duke of Cornwall and York. For some days previously to Jan. 24th the children of His Royal Highness had been suffering from an ill-defined feverish malady, and on Jan. 24th he himself complained of feeling ill, although for a few days previously he had not felt himself. On Jan. 24th His Royal Highness went to Osborne and on arriving there he began to be much troubled with cough and took to his bed. His temperature then was 102° F. and his pulse-rate varied from 80 to 86. On Jan. 25th and 26th he continued in much the same condition, the cough being very troublesome. On Jan 27th a slight friction sound was detected at the left base and the patient had a very bad night. Throughout Jan. 28th he remained very restless and uncomfortable, having no appetite, a furred tongue, and pain in the epigastric region, which last symptom was probably due to the almost continuous cough. He again passed a very restless night. On Jan. 29th a slight redness on the forehead was noticed, the cough continued to be very troublesome, and the patient passed a bad night. On Jan. 30th the temperature was still 102°, nausea was present, and he complained of a feeling of being unable to breathe; air entered badly and respiration was almost entirely abdominal. He had slight delirium, with occasional vomiting, the blush on the forehead was more marked, and one gland behind either sterno-mastoid was perceptible. On the night of Jan. 30th His Royal Highness slept for two hours with the aid of soporifics and a definite rash was beginning to appear. At 6 A.M. on Jan. 31st the rash was profuse, elevated, and very sensitive to the touch; all the glands were enlarged. From this time onwards convalescence set in and His Royal Highness rapidly improved. The illness was undoubtedly a very severe attack of German measles.

MAX VON PETTENKOFER.

THE death of Professor Pettenkofer under tragic circumstances removes from among us one of the founders of public hygiene. From the first he turned his attention to the chemical side of the study of medicine, and he had ample opportunities offered him for study at the universities of Munich, Giessen, and Würzburg. Pettenkofer's views on cholera will be found in an original article which he contributed to THE LANCET of Nov. 1st, 1884, p. 769. Though at one time he held what have since proved to be erroneous ideas of the germ theory of disease, yet he was right in maintaining that pure water and the rational disposal of sewage were the most powerful factors towards upholding the public health. So strongly was he convinced of the truth of his views that he undertook to swallow a cholera broth to demonstrate the harmlessness of the cultivations. He did it and luckily for himself without ill effect, but he must have been

[1] THE LANCET, Jan. 30th, 1897, p. 331.

too much a man of science to have attached any significance to his solitary experiment. But the story suffices to show the intense earnestness of Pettenkofer as an investigator and the sincerity of his efforts to throw light upon a terrible scourge with a view to its prevention. We now know that Pettenkofer's views on sanitation, pure air, and pure water are correct and since the time when he expressed his views we have had ample practical confirmation of them. None will dispute that with the increasing attention that has been given to these specific matters the health of the people in all parts of the world has improved or that Pettenkofer, though an obstinate sceptic in certain matters, was a great sanitarian. Pettenkofer also turned his attention to many physiological problems of the utmost importance. His famous researches which established the quantitative relations between the air inhaled and exhaled by animals have been proved to be a valuable contribution to our knowledge of the metabolic processes of the animal body. Pettenkofer in conjunction with Voit made some most important observations on the effect of muscular exertion upon the consumption of oxygen and the production of carbonic acid. A related research was also conducted by these investigators on the functions of particular nutritives in the animal body which involved laying down a theory of metabolism. In these researches Pettenkofer worked out his now classical method for the estimation of carbonic acid gas in respired air and in the atmosphere. This method, as is well known, depends upon the action of carbonic acid upon baryta water, the gas being absorbed with the formation of barium carbonate. Doubtless his experiments on the processes of nutrition led him to seek a means of detecting bile in urine. The Pettenkofer test for biliary acids which he subsequently discovered depended upon the formation of a train of colours when urine containing bile was treated with common syrup and sulphuric acid. The most marked colour produced was a beautiful purple. The test has since been modified in various ways, the most important improvement being the use of glucose instead of cane sugar. Glucose does not char when dissolved in strong sulphuric acid, whereas cane sugar does, and this occurrence is apt to mask any colour that may be produced. The various schools of hygiene throughout Germany contain professors of public health who were formerly pupils of Professor Pettenkofer. The veteran *savant* died at the age of 83 years and such a great length of life was consistent with his precepts.

THE CRUELTY OF COMPULSORY RETIREMENT.

A CORRESPONDENT is moved by "the lamented death of our beloved Queen, and upon contemplation of the many glorious and magnificent achievements of Her Majesty's later years," to write to us upon the subject of the injustice and cruelty of compulsory retirement. There is liberty in most things, he says, but in the matter of labour liberty is in some quarters positively denied. Our correspondent further points out that the moment a man suddenly ceases from his wonted labour he begins to deteriorate, and instances a number of men and women who have done good work in old age. There is no doubt that a hard-and-fast rule of retirement acts in many cases both unjustly and injuriously—unjustly because age has nothing to do with a man's capacity for work, and injuriously because in some cases the retirement comes when the ripe experience of the worker is at its best. The old proverb, "A woman is as old as she looks and a man is as old as he feels," is a very true one, and it is ridiculous to say that no one is fit for work after 60. Some men are old at 40 while others are fresh and juvenile at 80, and the personal equation must never be overlooked. Compulsory retirement, so far as we know, only exists in Government offices and hospitals. In trades there is nominally no compulsory retirement, but if an artisan is out of work at the age of 60 he will find hardly any employer who will give him more work although the same employer would probably have no hesitation in keeping on a man who had grown up to the age of 60 in his employment. In this way retirement is to a certain extent compulsory, for if a man cannot get work he is compelled to cease from it. But in the liberal professions we think that compulsory retirement does in many cases result in harm. Supposing that the 65-year rule had obtained in the Church we should long ago have been deprived of the services of the present Metropolitan, a loss which would have been very great. It would be undoubtedly difficult to decide without giving offence as to when a man became unfit, but that some modification should be made in the present inelastic system of compulsory retirement is, we think, certain.

SUTURE OF WOUNDS OF THE HEART.

THE *Medical Record* of New York recently contained an important paper on this subject by Dr. L. L. Hill. A wound of the heart may be produced by a stab or by a blow upon the chest, especially after a full meal, when the distended stomach pushes the heart upwards and forwards and causes a larger area of the organ to come in contact with the thoracic wall. When hæmorrhage into the pericardium is not arrested a fatal result is inevitable, for when the limit of pericardial distensibility is reached the heart is unable to dilate and the cardiac movements are mechanically stopped. Dr. Hill therefore insists that it is the duty of the surgeon to operate in every case of wound of the heart. It is as important to do so as to relieve a strangulated hernia. In 45 collected cases in which injuries caused rupture of the heart without opening the pericardium a fatal result always ensued. Only one patient survived as long as 14 hours. Of patients operated on for heart wounds 41 per cent. have recovered, as against 10 per cent. of those on whom no operation was performed. Operators agree that for closing a wound in the myocardium interrupted sutures are preferable to continuous sutures. They should be close together and not involve the endocardium. Silk is the best material. The needle should be similar to that used for intestinal suture. The suture should be passed and tied during diastole. The first suture may be used to steady the heart and to facilitate the passage of others. Ollier was opposed to the use of a general anæsthetic, but if the pulse was strong and the general condition was good chloroform might be given. Parrozzani operated in two cases without anæsthesia and observed only slight movement when he cut the skin and when he passed sutures into the myocardium. Dr. Hill narrates the two following cases. A girl, aged eight years, carried in her waist a needle two and a half inches long which was driven into her heart in falling against a tree. She was brought to his house with anxious countenance, rapid and weak pulse, and laboured respiration. The needle had entered the left fifth intercostal space and the head could be seen moving under the skin with the cardiac pulsations. 10 drops of a 4 per cent. solution of cocaine were injected under the skin and an incision an inch in length was made down on the needle, which was extracted with dressing forceps. The wound was immediately closed. Recovery followed. In the second case a man, aged 28 years, received a stab in the left fourth intercostal space a little inside the nipple. The limbs became relaxed and the pulse was hardly perceptible. The sounds of the heart were indistinct and the area of cardiac dulness was increased. Evidently the pericardium was filling with blood and the heart's action would soon be stopped. External hæmorrhage was slight. The blood was let out by enlarging the opening in

the pericardium and the patient's condition at once improved. He recovered though pericarditis followed. To expose the heart for the suture of wounds Dr. Rotter, writing in the *Münchener Medicinische Wochenschrift* of Jan. 16th, 1900, p. 79, has recommended, as the result of experiments on the cadaver, that an incision commencing three-fifths of an inch from the left edge of the sternum be made outwards along the lower border of the third rib for a distance of four inches and a similar incision along the lower border of the fifth rib for about three and one-fifth inches. The external ends of these incisions are connected by a third one. The incisions include the whole thickness of the thoracic wall and open the left pleural cavity. The fourth and fifth ribs are divided and luxated from their sternal attachments and the whole flap, including the soft parts and the ribs, is turned inwards, like a door on its hinges. The only arteries which have to be ligatured are the intercostals. The lung projects into the wound and is pushed outwards and held aside while the pericardium is opened by an incision extending from the upper and inner to the lower and outer angle of the opening in the thorax. The heart is so completely exposed that even the posterior surface can be reached. If still more space is required the third rib may be included in the flap.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

WITH regard to this Fund we learn that the honorary secretaries are authorised to state that there is no intention of making any alteration whatever in the title of the Fund. Its full title is, it should be remembered, "The Prince of Wales's Hospital Fund for London to Commemorate the Sixtieth Year of the Queen's Reign." We are glad to have the opportunity of giving publicity to the above statement and are equally pleased to see the decision which has been arrived at. First of all, there is the sentimental reason. As the Preacher remarked, in a slightly different sense, "A good name is better than ointment," and names, without doubt, have a great influence. The title of the Fund could not be altered with any regard to the new position of its Royal founder without doing away with the memorial idea. Secondly, there is the practical side to be considered. The Fund has been known under its old name ever since its inception; subscribers have got accustomed to the title, large legacies and bequests may have been left to the Fund which if the name of the Fund were altered would have to be rebequeathed and, therefore, probably legal worries and expenses would have to be entered upon. For all these reasons we are glad to know that the old title will be kept, a title which will ever recall the sympathy of the Heir Apparent with the wants of the poor and needy, as well as the memory of the gentle, kindly monarch so lately entered on her rest to whom sorrow and suffering never appealed in vain.

A METHOD OF DISTINGUISHING THE BLOOD OF DIFFERENT ANIMALS.

IN the *Deutsche Medicinische Wochenschrift* of Feb. 7th Stabsarzt Dr. Uhlenhuth describes some experiments which he has made with human blood and also with that of a number of the lower animals, the result being that he believes that he has discovered a specific reaction for human blood and also for that of the common fowl, the horse, and the ox. The process of testing for ox-blood is described by him at length as follows. At intervals of from six to eight days about 10 cubic centimetres of defibrinated ox-blood were injected into the peritoneal cavity of a rabbit and after about five such injections the blood serum of the animal was fit for use. In the next place samples of the blood of a number of different animals were diluted with about 100 times as much ordinary water, making pale red solutions of about an equal depth of colour. The insoluble stroma was removed either by subsidence or filtration. Of each of the clear solutions thus obtained about two cubic centimetres were put into test-tubes of about a quarter of an inch in diameter, and then mixed with an equal quantity of a solution containing 1·6 per cent. common salt—i.e., twice the strength of physiological salt solution. It is essential to use this particular salt solution, for the normal serum of the rabbit mixed with plain water gives rise to a turbidity which might interfere with the recognition of the specific turbidity. With physiological salt solution the addition of rabbit's serum never causes turbidity. Dr. Uhlenhuth employed in his experiments both human blood and also that of the ox, horse, ass, pig, sheep, dog, cat, stag, fallow-deer, hare, guinea-pig, rat, mouse, rabbit, common fowl, goose, turkey-cock, and pigeon. To each of the test-tubes there was now added from a tube drawn to a fine point six or eight drops of the serum of the rabbit which had been injected with the blood of the ox, whereupon there was seen in the solution of ox-blood a distinct turbidity which was very evident by transmitted sunlight. The contents of all the other tubes remained perfectly clear. In course of time the turbidity increased and ultimately a copious flocculent deposit fell to the bottom. Normal rabbit's serum causes no turbidity in solutions of ox-blood. By the addition of a few drops of serum from the injected rabbit it was therefore possible to recognise ox-blood. In a precisely similar manner injections of human blood were given to rabbits, and serum from the animals was added to the 19 specimens of blood above mentioned, the result being that the solution of human blood, and that alone, became turbid and threw down a deposit. All the other solutions remained perfectly clear. Normal rabbit's serum causes no turbidity in solutions of human blood. This reaction, therefore, enabled human blood to be distinguished with certainty from the other kinds of blood above mentioned. The reaction was extremely delicate, only traces of blood being required for the determination of the species of animal to which it belonged. By it Dr. Uhlenhuth succeeded in recognising samples of human blood, ox-blood, and horse-blood which had been allowed to dry on a board and after four weeks were dissolved in physiological salt solution for the purpose of examination. His experiments were made in the Hygienic Institute of the University of Greifswald. If his conclusions are verified the reaction will obviously be of great use in medico-legal inquiries.

THE WHITE CROSS LEAGUE AND QUACKERY.

WE have received from the White Cross League two excellent pamphlets, entitled, "Quacks and their Advertisements," published at the offices of the League, 7, Dean's-yard, with a view of protecting young persons and others from the machinations of a dangerous class of impostors. The particular quacks aimed at are those who trade upon the ignorance and fears of youth, who begin by alluring their victims by advertisements of cures for supposed sexual weakness or sexual disorders, and "remedies" for conception, and who end by extorting large sums of money either by selling sham, and possibly dangerous, medicines, or by the simpler and more lucrative process of blackmail. The pamphlets in question are not intended for the perusal of those liable to fall into the hands of the sexual quack, but are rather for the instruction and guidance of parents, clergymen, and others from whom the word of warning should most effectively come, but who are often silent simply because their observation has not been aroused, while their knowledge of the dangers to be feared and of the means of guarding against them is insufficient. We

commend them to the study of medical practitioners who cannot be too well informed as to the methods adopted by the quack in order that they may be prepared to counteract his influence. Probably not every medical practitioner, for example, is aware of the "dodge" of sending to the applicant who answers an advertisement medicine calculated to produce precisely those symptoms most likely to alarm him, while a second instalment of less injurious character follows, with the result that the symptoms caused by the first doses abate and the quack claims (and the patient believes) that the treatment has been beneficial. In the second pamphlet we note a useful discussion of the manner in which dangerous advertisements may, to some extent, be put a stop to. These, when they appear in the public press, cannot be dealt with under the Indecent Advertisement Act which refers to notices affixed in public places or in urinals, and does not profess to purify newspapers. It is suggested, however, that in the case of a newspaper a letter to the proprietor may satisfy him that an advertisement, even though outwardly harmless, is giving offence to a section of his readers. We believe that some good may be done in this way, particularly if the persons remonstrating are of known position and influence; but, on the other hand, we cannot forget that advertisements which were patently and obviously offers of drugs to be used for the purpose of procuring miscarriage were accepted by hundreds of newspapers in all parts of the country. Until recent prosecutions of the advertisers and plainly spoken warnings uttered from the judicial bench caused the proprietors of certain newspapers to realise that their conduct was not only scandalous but actually dangerous to themselves the abuse was not abated.

"A FINE FOR DYING."

AT the present day, when so many people spend a portion of the year abroad, and particularly when invalids of various kinds seek the hotels of foreign resorts in consequence of medical advice, the circumstances related in our last issue (p. 444) under the above heading have a wide interest. Briefly stated, the matter is this: a gentleman, advised by his medical man, goes to Caux and stays in a hotel there. He dies and his relatives are charged £40 compensation by the hotel. The relatives on their return inform the medical man, who sends us their letter for publication as a warning to other practitioners. In sympathising with people who besides the loss of a relative are promptly mulcted of a considerable sum we must not entirely overlook the other side of the question. To a hotel a death may be a matter involving serious loss of reputation and of business. In the particular instance which concerns us we have no details of the nature of the patient's illness and the manner of his death. Presumably there was nothing unusual in either nor anything particularly likely to be damaging to the hotel should it become matter of common knowledge. Such being the case we think the charge made was certainly excessive. Moreover, it seems to us a most unreasonable procedure to make a fixed charge of £40 in every case where death occurs at the hotel. It is easy to imagine cases in which this charge would be much under the cost incurred by the hotel, just as in the present instance it was probably very much above it. In cases of infection, for instance, the necessary cleansing, possibly the closing of part or all the hotel, might well lead to loss of business far exceeding £40. On the other hand, in a case of what we may call ordinary death the loss to a well-managed hotel should be little beyond a few incidental expenses and should certainly be covered by far less a sum than that which was here charged. A moral, at any rate, may be drawn from this case. When a patient is going abroad obviously it may save his friends annoyance if their medical adviser should mention this matter to them and be able to give them some idea of what is likely to arise in the untoward event of death overtaking their sick relative.

THE COMMUNICABILITY OF GLANDERS.

THE President of the Board of Agriculture has appointed a committee to conduct experimental investigations into the communicability of glanders. The influence of mallein when repeatedly administered in arresting or curing the disease is also to be made the subject of inquiry. The committee will consist of Mr. A. C. Cope, M.R.C.V.S. chief veterinary officer of the Board of Agriculture (chairman); Professor J. McFadyean, M.B., C.M., B.Sc. Edin., M.R.C.V.S., principal of the Royal Veterinary College, Camden Town, London, N.W.; Mr. William Hunting, F.R.C.V.S., one of the veterinary inspectors of the London County Council; and Mr. J. McIntosh McCall, M.B., C.M. Glasg., M.R.C.V.S., assistant veterinary officer of the Board of Agriculture. Mr. A. H. Berry, M.R.C.V.S., of the Board of Agriculture, will act as the secretary to the committee.

MR. BURDETT-COUTTS AND THE REPORT OF THE SOUTH AFRICAN HOSPITALS COMMISSION.

As our readers cannot fail to have observed, Mr. Burdett-Coutts has lost no time in publishing long and elaborate communications in which he analyses the report of the Royal Commission on the hospitals in South Africa and subjects it from beginning to end to a very severe and trenchant criticism commenting at the same time very adversely on the conduct of the inquiry. We may safely leave Lord Justice Romer and his colleagues to take care of themselves and their report at the proper time and place. The whole question must engage the attention of Parliament and we make no doubt that some reply will be forthcoming to Mr. Burdett-Coutts's strictures. We hope to see the matter fully and fairly discussed, for it is one, if ever there was one, which demands to be very earnestly and dispassionately considered. We were not among those who denied *in toto* the existence of the state of things described by Mr. Burdett-Coutts. But we wanted to know, like everybody else, how far this state was unavoidable under the circumstances, or whether it was attributable to the negligence, incapacity, or fault of anyone. The mere fact of Lord Justice Romer having been appointed to preside over the Commission gave us the assurance that the inquiry would be thoroughly and dispassionately conducted. The report, which, be it remarked, was signed by all the Commissioners, struck us as an able and eminently fair public document. Mr. Burdett-Coutts thinks otherwise. He will have none of it, and enters a strong protest against it. We must be content to await further developments. We may, however, say this in the meantime in regard to the war in South Africa, because it must be patent to everybody now. Every day brings the fact to light more forcibly that neither this country nor the Government, nor, indeed, anybody, had formed any correct estimate of the very formidable nature of the undertaking. The war preparations were designed on altogether too small a scale. Medical provision was made for an army of some 50,000, whereas it should have been, as it turned out, for nearer 250,000. The transport in the country at the time of Lord Roberts's arrival was better adapted for peace manœuvres than for a large war, whose operations had to be conducted over an enormous extent of territory. But for these facts it seems to us that Mr. Burdett-Coutts would have found no ground for his bitter criticism. In order to obtain a correct view of

this war the military despatches, as well as the report of the Commission on the medical service and Mr. Burdett-Coutts's comments, require to be studied—a long and somewhat formidable task. The situation set forth in Earl Roberts's despatches was an altogether exceptional one. He had to undertake and carry out a very rapid plan of campaign and in order to do this successfully he had to incur certain risks by setting aside for a time the ordinary rules and precautions of war, and it was at this time and under these conditions that there occurred a very severe outbreak of enteric fever. The question is how far was it possible for anyone to foresee, and having foreseen it to prevent, the sad sequel.

THE ERITH DISTRICT COUNCIL AND THE MEDICAL OFFICER TO THE ERITH SANATORIUM.

MR. JOHN ELLIOT, medical officer to, and also founder of, the Erith Sanatorium, has been called on to resign his post by a majority of one at a meeting of the Erith District Council, and, according to a report of the proceedings in the *Erith Times* of Feb. 8th, it was on information verbally supplied by a subordinate nurse belonging to the establishment that this measure was decided upon. Needless to say that should such really prove to have been the case the intervention of higher authority is urgently called for and will no doubt be forthcoming. It is worthy of note that among the councillors who opposed Mr. Elliot there should be the mover of an amendment objecting to the forwarding of a vote of condolence to the Royal Family upon recent events.

AN ANOMALOUS CASE OF WORD-BLINDNESS WITHOUT APHEMIA OR AGRAPHIA.

PROFESSOR BRISSAUD of the Salpêtrière has made an interesting communication on the above subject, an account of which has appeared in the *Archives de Neurologie* for January. The case is one of word-blindness where the question arose as to whether the cerebral lesion was situated in the parietal (angular) region or in the occipital (calcarine) region and whether it was cortical or subcortical in position. The case was that of a man, aged 57 years, who was admitted to hospital for a severe attack of enteritis. His friends stated that he had lately failed to recognise ordinary objects and was inclined to oddities of conduct. The patient seemed to be well behaved on admission and after some effort and difficulty he succeeded in giving the following history. For a certain length of time prior to admission he found himself quite unable to read although he was, and still appeared to be, capable of writing. He continued in the extraordinary condition of being absolutely unable to read his name and address which he had just written with his own hand. He only saw the black lines of the writing on the white background of the paper, but they conveyed to him no significance visually. Hemiopia was also found to be present, but without hemiplegia. He continued in a febrile condition, passed into coma, and died the same day. At the necropsy the following pathological changes were discovered—viz., an old cortical softening involving the inferior four-fifths of the cuneus and the whole of the calcarine fissure as well as almost the whole of the lingual lobule on the left side; a secondary degeneration of the tapetum and of the optic radiations on the same side, but without lesion of the inferior longitudinal fasciculus or parietal cortex or any other subcortical region. The degeneration of the tapetum could be traced into the splenium of the corpus callosum and thus into the right hemisphere where it seemed to terminate in the tapetum and calcarine region of that side without affecting the optic radiations or the white substance subjacent to the calcarine cortex. The clinical and pathological interest of the case lay in the fact that owing to the intact condition of the auditory and visual word centres—the superior temporal and angular gyri—these centres could incite their respective kinæsthetic centres of word-utterance and word-writing to activity and thus both writing and speaking were possible, but the local destruction of the calcarine and adjacent cortex on the left side (primary visual cortical centre) produced not only hemiopia but also sufficient defect and disturbance in the secondary visual centre (visual word centre) of the same hemisphere to prevent the visual recognition of written or printed words.

ALE AND BEER IN THE SIXTEENTH CENTURY.

THE composition of ale and beer has always been of interest to members of the medical profession. Dr. Andrewe Boorde, who lived in the reign of Henry VIII., gives a full account of the composition of most of the beverages which were in use in his own time. He considered that water was not "holsome sole by it selfe for an Englyssheman" because it was "colde, slowe, and slacke of dygestyon." Ale, he said, for an Englishman was the natural drink. It was in his time made of malt and water fermented by yeast. It had, in his opinion, to be fresh and clear, not ropy or smoky. It appears to have been drunk very shortly after it was made, for he says that it ought not to be drunk under five days old, and that new ale was unwholesome for all men. He observed also that sour ale was good for no man, an observation which has been confirmed by subsequent experience. Contrary to the opinion of some modern brewers, he considered that barley malt made the best ale. He confessed, however, that in spite of its good qualities the beverage engendered gross humours, but he added that it made a man strong. In his description of the composition of ale no reference is made to hops and it appears that they were not used in the drink which he called ale for he looked upon other ingredients except those which he mentioned as being adulterations. The composition of beer was different. It was made of malt, hops, and water, and was, he observed, the natural drink for a Dutchman. Of late days it had indeed been used in England but unfortunately with detriment to many Englishmen, and it was especially harmful to those who suffered from colic, "for the drynke is a colde drynke," he observed. Yet he said it made a man fat—a point on which the observer could satisfy himself by examining the faces and other parts of the persons of Dutchmen. The beverage had, however, one good point, which was that if it were well served in good condition and not new it qualified the heat of the liver. Dr. Boorde was a great traveller and amongst other things he especially noticed the condition of the food and the drink in all the places which he visited. Of the ale of Cornwall he formed a very low estimate; it looked white and thick, "as if pygges had wrastled" in it, and he gives some unsavoury particulars as to the ill-effects of drinking this beverage into which, perhaps, it is hardly necessary to follow him. In Boorde's time it does not appear that Scotland was celebrated for good ale as a general rule. Although fish and flesh were to be had there in plenty, the ale, he says, was evil, with the sole exception of that brewed at Leith. Dr. Boorde was extremely severe in the punishments which he thought should be meted out to brewers of bad ale and to those who gave short measure. He gave it as his opinion that they ought to be placed in the Thames up to their chins and three inches above, and suggested that when they came out they would have to shake their ears as a spaniel that verily came out of the water. Dr. Boorde devotes one chapter of his book to soups, stews, and other articles of diet which would now be classified under the general heading of invalid food.

Amongst his recipes he recommended ale brews and caudles for weak men who could not eat solid meat. In many country districts these old-fashioned compositions are still used and sometimes perhaps with satisfactory results.

THE TRAFFIC IN OLD HORSES.

IN our issue of Dec. 3rd, 1898, p. 1492, in an annotation under the above heading, we called attention to the fact that an Order had been issued by the Board of Agriculture under which it should from Jan. 1st, 1899, be unlawful to convey from any port in the British Isles to any place outside the British Isles "any horse which, owing to age, infirmity, illness, fatigue, or any other reason, cannot be so conveyed without cruelty during the intended passage and upon landing." Offences under this Order were to be dealt with as under the Diseases of Animals Act, 1894. On Jan. 8th, two men, Ernest Ellis and Charles Wilson, were charged at the Thames Police-court with cruelty to 13 horses by leading them when unfit to travel. One horse was so weak and lame that it fell down in the road and the foot of another was partly destroyed. The horses were going to Rotterdam and had come from Stratford. Inspector Rogers said that there was no Government inspector to look after such horses. The wharf from which they were to be shipped belonged to the London and India Joint Docks Committee. They had an inspector, but he never interfered. Mr. Dickinson said that the defendants were only the agents of someone else and fined them £5 and £2 2*s*. costs each. We should be glad to know why such cases are not dealt with under the Order of the Board of Agriculture and the Diseases of Animals Act. If the accused, whose delinquency we have just described, had been thus proceeded against it seems that they could have been fined (apparently, under Section 51) a sum of £5 for each animal, or £65 in all. As we have said upon previous occasions, this infamous traffic ought to be stopped altogether. Not only does it give rise to gross cruelty, but it must be remembered that the flesh of these wretched animals is used for human food. Possibly it returns here in the shape of "delicacies," but even if it does not it is not fitting that we should assist in poisoning our neighbours on the other side of the North Sea.

ARSENIC IN ARTIFICIAL MANURES.

IN an annotation in THE LANCET of Dec. 22nd, 1900, p. 1828, we reported the presence of arsenic in artificial manures, and the question arises as to whether the quantity of arsenic thus present would be absorbed by plants and thus afford a possible explanation of the presence of arsenic in malt and hops. Our observations have given rise to much discussion amongst agriculturists, and especially amongst the manufacturers of superphosphate. The opinion seems to be generally held by agricultural chemists that the quantity of arsenic present in superphosphates might safely be neglected as it is so minute. In a communication sent to us by a firm of artificial manure manufacturers Dr. Stützer (the professor of agricultural chemistry at the University of Königsberg) arrives at the conclusion that the percentage of arsenic in the soil after 49 years of experiments, as at Rothamsted, would have risen to 0·0002. Of course, from these figures it would appear that we have to deal with such very minute quantities that there cannot be any question whatever of poisoning the plants through arsenic. We may point out, however, that this calculation is based upon the assumption that the quantity of arsenic in sulphuric acid is generally from 0·05 up to 0·10. Now according to the analysis of the sulphuric acid concerned in the beer-poisoning epidemic, as given in THE LANCET of Dec. 1st, 1900, page 1602, Professor Stützer will find that the amount of arsenic exceeded 1·4 per cent. In view of this fact his calculations are of no value whatever. Professor Stützer, however, points out that plants, especially in the state of germination, are just as sensitive to arsenic as men and animals and no ill effects have, as a matter of fact, followed the use of superphosphate as a fertiliser. On the contrary, the crops increase under the influence of superphosphate.

THE ALLEGED DRYNESS OF AIR IN ROOMS WARMED BY GAS FIRES.

COMPLAINT is frequently made as to the drying effect of gas fires on the air of the room, so that any information on the subject calculated to lead to this effect being avoided is welcome. According to Mr. Thomas Fletcher, F.C.S., a well-known gas-stove maker, the feeling of dryness is not due to the reduction of the moisture in the air but to some of the products of combustion escaping into the room. He regards the unpleasant feeling of dryness in the throat and nostrils as being caused by a trace of sulphur in the products of combustion escaping, a statement which would appear to be verified by the fact that a strip of wet blue litmus paper exposed to the air quickly reddens, pointing to the conclusion that the alleged fault of gas fires is caused entirely by defective flues. According to hygrometric measurements he shows that the percentage of moisture maintained in a room was much the same with a gas fire as with a coal fire. The results are much the same whether the stove has an air-warming arrangement or not, apart from the radiant heat it produces. The percentage amount of moisture was arrived at by using a wet and a dry bulb thermometer. The difference in degrees between the two thermometers was multiplied by six and the product deducted from 100, which was regarded to give approximately the percentage of moisture, taking complete saturation as 100. Mr. Fletcher states that this method is perfectly reliable for comparative observations between the effect of gas fires and coal fires at the same temperatures. It is concluded that in an inhabited room from 58 per cent. to 72 per cent. of moisture at about 62° F. will be pleasant, and this is easily obtained with either a coal fire or incandescent gas fire except when the outer air is completely saturated with moisture. Apart from the observation on the discomfort caused by sulphur compounds escaping in the products of combustion the feeling of comfort and warmth depends, as we should have supposed—although the point has not had sufficient attention paid to it in regard to the management of sick rooms and hospitals—rather on the amount of moisture in the air than on the actual temperature as shown by a thermometer.

BRAIN INJURY FOLLOWED BY WHISTLING SPELLS.

DR. WILLIAM KRAUSS has recorded in the January number of the *Journal of Nervous and Mental Disease* an interesting case of brain injury with consequent periods of whistling, which attracted much attention at the time and also possessed considerable clinical interest. The case was that of a man, aged 27 years, of Polish descent, by occupation a herdsman in the East Buffalo stockyards. He was a man of powerful build and physique, about six feet in height and weighing nearly 230 lb. Some months prior to the accident which brought on his present illness he had had a stroke of left-sided hemiplegia from which he was recovering. He slowly regained the use of the left arm and leg and was able to resume his occupation. On the morning of Dec. 30th, 1898, he was found unconscious and lying along a railway line with three scalp wounds, having probably been struck by a passing train during the night. On examination there was a depressed fracture of the skull three inches above and

one inch behind the left ear. No other important injuries were noted except a few body wounds of little importance. He was immediately trephined and the depressed bone was removed. On removing him to bed it was necessary to strap his arms as he constantly tried to remove the bandages and dressings. About 10 o'clock at night "he began to whistle, not the popular songs of the day, but the whistle-calls he was accustomed to use in calling or driving his flocks. He would continue whistling for about one minute, then would cease for five or 10 minutes, and kept this up for regular intervals till he died," four days after. The whistling was pitched always in the same key and was of the same intensity throughout, and at no time was it possible to distinguish any melody. It was audible throughout the ward and attracted the attention of patients and nurses. "To the physicians in attendance it was a strange experience to hear these whistle-calls coming from a patient in a state of unconsciousness." It was impossible to rouse the patient at any time after the accident, and he died unconscious but whistling until a few minutes before death. He was treated with milk diet and stimulants in abundance but never rallied. There was complete loss of control over the bladder and rectum; the pulse was slightly lowered, but the temperature was normal. The case is a unique one, the whistling spells entitling it to publication, but no explanation is advanced to account for this peculiar phenomenon.

ARSENIC IN BEER.

ALTHOUGH the history of the beer-poisoning epidemic is now pretty well known, yet the able report of Dr. G. S. Buchanan which he has just presented to the Local Government Board must be regarded as a valuable document on the question. It is, up to the date it was issued, a complete account of the epidemic. It deals with the number of persons attacked by the epidemic, the clinical characters of the epidemic malady, and the number of fatalities, and discusses the technical processes in beer that have led to its contamination. The position, it appears to us, is so clearly defined in this report that any further inquiry, relating at any rate to the beer-poisoning epidemic, would seem unnecessary. But, as Dr. Buchanan points out, important questions have arisen concerning the safety in regard of arsenic of all chemically manufactured sugars used in this country for brewing and for all other purposes, and also concerning the precautions requisite to safeguard the public against risk from introduction of arsenic along with chemical ingredients of beer and other articles of food or drink. On this account the desirability of expert examination of the whole subject of arsenic in relation to food in its medical, chemical, and technical aspects becomes apparent, and therefore a very wide field of investigation is presented which will impose considerable labours on the Commission which the Government has decided to appoint. We have expressed the opinion that no further investigation is needed in order to decide that increased legislative measures are required to provide absolutely against the possibility of beer being contaminated with arsenic. Dr. Buchanan's report confirms our view. An abundance of material is already at hand which should easily enable the Government to determine exactly the direction in which legislation could proceed with rapid and wholesome effect. By all means let the exhaustive inquiry into the presence of arsenic in most foodstuffs proceed, but the public need not wait for the report of such a prolonged investigation for legal protection from arsenic poisoning in beer.

AT the quarterly meeting of the committee of management of the Royal Free Hospital, held on Jan. 30th, the following motions, proposed by the chairman, the Hon. Mr. Justice Bruce, and seconded by Captain H. M. Jessel, M.P., were passed unanimously—viz.:—

The committee of management of the Royal Free Hospital record their profound sorrow at the death of Her Most Gracious Majesty Queen Victoria who, as the Princess Victoria, was a vice-patron, and during the 64 years of her reign was the patron of the hospital, and in 1837 granted to it the highly esteemed privilege of being named the Royal Free Hospital, and on many occasions has shown acts of kindness and generosity to the institution.

The committee respectfully offer to His Majesty King Edward VII., to Her Majesty Queen Alexandra, and to the other members of the Royal Family most heartfelt condolence on the loss which they and the empire have sustained, and beg to assure His Majesty, who has for many years been the vice-patron of the hospital, of their loyalty and devotion to his throne and person.

A PUBLIC MEETING will be held at the Town Hall, Rosebery-avenue, E.C., on Friday, Feb. 22nd, at 8 o'clock, to consider the question of the prevention of consumption in Finsbury. The chair will be taken by the Mayor of Finsbury, who will be supported by Sir William Broadbent, Sir James Crichton Browne, Professor MacFadyean, and others. Seats will be reserved for ticket-holders up to 7.45 P.M.

LOYAL addresses of sympathy and homage have been tendered to the King by the council of the Prince of Wales's Hospital Fund for London, the council of the Metropolitan Hospital Sunday Fund, the members of the Royal Medical and Chirurgical Society, the governors of Middlesex Hospital, of the Hospital for Consumption and Diseases of the Chest, Brompton, and by many other medical institutions.

AT a meeting of the Metropolitan Hospital Sunday Fund, held at the Mansion House on Feb. 7th, Sir William S. Church, P.R.C.P. Lond., was elected a member of the Distribution Committee in the place of the late Dr. Sedgwick Saunders.

A TELEGRAM from the Government of Mauritius to the Colonial Office, dated Feb. 8th, states that for the week ending Feb. 7th there were 16 fresh cases of plague, of which seven were fatal.

REFLECTIONS ON THERAPEUTICS.

BY HARRY CAMPBELL, M.D., B.S., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL AND TO THE WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

VI.[1]

SOME GENERAL PRINCIPLES.

I MUST now ask attention to certain general principles which I have expounded at some length in a work on the Causation of Disease, and I shall seek to express myself in terms as simple as possible, convinced as I am that a thorough understanding of the principles in question is necessary to a proper conception of disease and its treatment.

Life a two-sided process.—First, then, I would ask the reader to keep ever before him the fact that life consists of the mutual interaction of the individual and his environment. In the case of unicellular organisms this truth is manifest, but we must never forget that it applies to multicellular organisms also—to man, to wit. As in the case of his amœboid ancestors inhabiting the salt ocean every active living cell in man's body is bathed in a saline

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of Jan. 5th (p. 51), 12th (p. 122), and 19th (p. 201), and Feb. 2nd (p. 348) and 9th (p. 420), 1901, respectively.

medium[2] containing nutrient substances and oxygen; and the essential vital changes of the body at large take place between the cells and their environing plasma. It is needful to have a clear conception of the term "environment." In the case of a multicellular organism such as man it consists of all those influences which operate from without upon the organism as a whole (the external body-environment) and upon the individual cells from within (the internal cell-environment). The former includes the solid external world and the atmospheric medium—its condition in respect of humidity and pressure, the solid particles, parasitic and others, suspended in it, and the vibrating influences operating through it—thermic, actinic, luminous, electrical, sonorous, and the rest. It further embraces the macroscopic parasites, food, drink,[3] and clothing. It is also convenient to regard exercise of the muscles as pertaining to the environment, and in a measure it is justifiable, since all muscle-contraction is essentially a working against external force, which at the time of the contraction is thus influencing the body from without in a specific way.

These external physical agencies not only act upon man in his purely physical aspect: through his organs of sense they play upon his mental side also, evoking sensations, perceptions, and other psychic states. It is, moreover, by means of similar agencies that man is influenced by the minds of others, living and dead, such influences constituting a mental, as distinguished from a merely physical, environment.

The internal cell-environment embraces the various influences which operate upon the individual cells within the body (these influences being, of course, largely determined by the external environment)—the cell-environing plasma, with its oxygen, food-stuffs, salines, effete matters, micro-organisms, and the thermic, electric, and other vibratory forces, including the nerve-impulses striking upon the cell from without.

Disease a two-sided process.—Inasmuch as life consists of the mutual interaction of the individual and his environment, disease, which is a mode of life, may be defined as an abnormal or morbid interaction between these two great life-factors. I am aware that to make this definition strictly logical it would be needful to define the term "abnormal." Its meaning is, however, sufficiently clear for my purpose, which is to emphasise the two-sided character of all morbid processes; each factor—that of the individual and that of the environment—shares in those processes, and we cannot exclude the one or the other from the causation of disease.

Heredity plays a part in the causation of all diseases.—A due appreciation of this two-sided character of disease enables us to understand the important share taken by heredity in its causation, for seeing that disease consists in a morbid interaction between the individual and his environment, and that the organisation of the individual depends essentially upon heredity—i.e., he is what he is essentially by virtue of his ancestry—it follows that we cannot eliminate the influence of heredity from any disease. When an individual develops such a disease as granular kidney or megrim, independently of any specific environmental agency, it must obviously—unless it is a sport of nature, an entirely new development—be inherited from some ancestor,[4] but when it arises from the action on the individual of some specific environment, such as a pathogenic microbe, heredity is apt to be lost sight of as a factor. One must, however, remember that whether an individual shall, or shall not, respond morbidly to a specific environment depends not upon that environment only, but also upon the inherited structural peculiarities of the individual himself. Some animals, for instance, are in no way injuriously affected by micro-organisms which to others are deadly. Thus the carnivora are practically immune from tuberculosis, and this immunity obviously depends upon organisation, which in its turn depends upon heredity—i.e., these animals are immune because of the immunity of their ancestors. Woods Hutchinson has suggested that this resistance of the carnivora to the attack of the tubercle bacillus has been acquired by the survival through ages past of such among them as have not succumbed to tuberculosis derived from devouring tuberculous animals, and there can be no doubt that the different resisting powers of different species, and of different individuals among the same species, to the attack of micro-organisms, has been in large measure brought about by elimination—by the operation of natural selection.[5] Such being the case, we see how impossible it is to ignore the influence of heredity in the causation of any of the multitudinous diseases arising from micro-organisms, such as tuberculosis, ague, rheumatic fever, and malignant tumours. And the same remark applies to every disease due to the action of a specific environment. Space does not permit me to develop this thesis at length, and for farther arguments in its support I must refer the reader to my larger work already quoted. I am most anxious that this great principle should be widely understood; ignorance of it is checking advance in many directions.

Characters acquired by the individual not inherited.—The subject of the inheritability of acquired characters—diseases among others—has of late years been brought prominently before the profession by Dr. Archdall Reid, and in the controversy which he has provoked much confusion has resulted from several of the disputants failing to understand the meaning of the term "acquired character." We must, then, first be clear what we mean by it. When germ and sperm unite there is started on its career a new being. The conflict of unlike hereditary tendencies derived from these two elements may lead to the development in the offspring of entirely new characters. Such characters, or natural variations as they are called, are capable of being transmitted to future generations, and it is upon them that natural selection operates, producing in the course of generations profound racial effects; but they are not *acquired* by the new being, though they are often spoken of as if they were; they develop *de novo*. Acquired characters are those impressed upon the new being by its environment; the organism is capable of being moulded by its environment in a multitude of different ways, and it is these *environmental mouldings*, as they might be called, which constitute true acquired characters. Thus all the changes wrought in the nervous system by education are acquisitions, as also are mutilations and the hypertrophy and atrophy of organs from use and disuse, these being due to peculiar influences working through the cell-environment.

Now a careful search by the most eminent biologists throughout the world during the last 20 years has failed to discover a single unmistakeable instance of such an acquired character being inherited. All the valuable acquisitions of the brain and nervous system die with the individual; and in the same way mutilations, such as the piercing of the ears, the circumcision of the prepuce, the docking of tails, though continued through many successive generations, have no effect whatever upon the offspring. If a man develops his biceps muscles to the utmost capacity his children are not born in consequence with these muscles larger than would otherwise be the case. Similarly, the imperfect development of the jaws and teeth among the civilised is not due to any hereditary defect consequent upon their imperfect use through many successive generations; it is acquired for himself by each individual and the defect is not transmitted. Were the children of parents presenting such defects fed from early infancy on coarse food necessitating the thorough use of the jaws and teeth, we should find these structures as well developed in them as in the primitive savage.[6] To mention one other case only here—gout is essentially an acquired disease due to a specific environment, and because the individual has led a gout-producing mode of life his children are not on that account rendered more liable to develop the disease, though they may undoubtedly inherit from him the tendency to respond in the same morbid manner to the same environment if they are exposed to it.

[2] The superficial horny cells of the skin are not thus bathed, but they are practically dead and in process of being shed.

[3] Be it observed that the respiratory and alimentary tracts are, strictly speaking, external to the body.

[4] It is well known to biologists that the mingling of unlike tendencies in germ and sperm may lead in the new being to which they give rise to entirely new characters—i.e., characters not belonging to any ancestor. Such new characters constitute natural variations; and it is the opinion of Weismann that one of the purposes served by sexual reproduction is the creation of such varieties, without which evolution by natural selection would be impossible. Now it is possible that variations thus arising may occasionally be pathological, and it might be argued that they afford instances of diseases in which heredity plays no part. It is, however, probable that such pathological variations, if they do occur, are rare, and they may for all practical purposes be disregarded.

[5] I have shown how by the elimination of the susceptible a race may become adapted to pathogenic microbes, such as those which give rise to malaria (see p. 231 *et seq.* "The Causation of Disease," 1889). Dr. Archdall Reid has independently advanced the same view (see, e.g., his work, "The Present Evolution of Man").

[6] It is, however, possible that sexual selection may have had some influence in causing the jaws of the civilised to be smaller among civilised than among primitive peoples.

Normality in respect of the individual and the environment.—In seeking to discover what constitutes the normal man and his normal environment the prime fact to remember is that neither can be defined except with reference to the other. If an individual can keep healthy in a given environment (a term which, as we have seen, refers to a highly complex series of conditions) he is normal as regards it, and it is normal as regards him; if he cannot, then each is abnormal as regards the other. A negro can keep well in parts of Africa which kill the white man and the white man can keep well in parts of Europe which kill the negro. The one is normal as regards the African environment, abnormal as regards the European; the other is abnormal as regards the African environment, normal as regards the European. And similarly as regards the environment, each may be regarded as normal or abnormal according to the individual living in it.

This relativity of normality has an important therapeutic application. From it we learn that we cannot regard an individual as absolutely abnormal because he cannot keep well in an environment in which the majority can. One who under average conditions suffers from megrim, asthma, gout, or rheumatism may under other conditions enjoy perfect health, and it is the business of the physician to find out what those conditions are. Thus there are few cases of spasmodic asthma so severe that they cannot be cured by residence in some particular region, could one only discover it, and in relation to such a region the sufferer is strictly normal. In like manner victims of gout, megrim, and rheumatism may throw off these disorders under altered conditions of life, being as regards these altered conditions perfectly normal. As a further illustration of the same principle I may cite the case of a lady who, while living in a London suburb where she superintends a household under somewhat harassing conditions, suffers from bronchitis, indigestion, eczema, and general nervousness, all of which disappear, leaving her in the best of health, when she goes to stay with a married daughter in Berlin, but only to reappear on her return to the old environment. We must not, however, push this principle too far. I do not wish to imply that an individual who can only keep well under carefully chosen conditions can be regarded as coming up to a high level of physical fitness. I merely wish to insist upon the relativity of normality. Individuals differ considerably in their ability to cope successfully with different varieties of environment. The more rigorous and varied the conditions under which an individual can keep well, the higher his level of physical fitness. Some there are who can retain their health in many different climes, who can undergo with impunity the severest hardships, who can resist the onslaught of the most deadly microbes, be guilty of all kinds of excesses, eat enormously and of the coarsest foods, smoke all day, and consume large quantities of alcohol, who can undergo great physical and mental toil—and in spite of all this remain in seemingly perfect health; though I am not going to argue that they can do all these things with absolute impunity. Such men, we say, are endowed with a magnificent constitution. Others there are who can only keep well under a comparatively simple and carefully chosen environment who must select a climate with the utmost care, live on the simplest food, avoid alcohol and tobacco, and undertake only moderate mental and physical labour. These must be regarded from the biological standpoint as inferior animals. Nevertheless, they often live longer than their more robust brothers, partly because they have to take greater care of themselves and are thus protected from many agencies which make for destruction, and partly also in some cases because, though apparently frail and constantly ailing, their death-resisting power is actually greater.

And here let me observe that it is a great mistake to measure a man's physical fitness by his stature and muscular strength, as is so often done. Rather should it be measured by his power of endurance and ability to resist death, both of which are independent of great stature and muscular development. The difference between a man of powerful and another of slender muscular build is much the same as that between the cart-horse and the racehorse: it is essentially a matter of breed. As a matter of fact, tall men are generally less enduring and shorter lived than small men, and very muscular men may be in many respects delicate. Dr. Hancock, who has had thousands of coolies under his supervision, tells me that it is precisely those who have the best muscular development and are thus most valuable to their masters who are most frequently carried off by cholera—who have the least germicidal power in respect of this disease.

Now, inasmuch as normality as regards the individual can only be defined in reference to the environment, and inasmuch as it is impossible to construct a rigid standard of normality for the latter, it is obviously impossible to construct a rigid standard of normality for the individual. Nevertheless we have a sufficiently clear notion of what constitutes a normal individual. Such a one must be sound in body and limb, as popularly understood, and he must be endowed with a fair average of intelligence and moral capacity; he must, moreover, be capable of living, under an average rigorous environment, to old age in good health, subject of course to those temporary departures from it which (under the most "easy" possible environment, and *a fortiori* under the influence of those definite pathogenic agencies which the average environment entails) are inseparable from life. Our conception of structural normality, therefore, should have reference not only to any one portion of the life of the individual, but to his entire vital span. If under an average environment, Bright's disease, rheumatic fever, ovarian cyst, strangulated hernia, cancer, or such like disease develops, the individual does not answer our test of normality, and viewed from this standpoint must be regarded as abnormal. If every individual of the community came up to the normal as just defined, then under a perfect system of sanitation the only deaths would be those due to accidental causes. And here I would point out that the hygienist has fallen into the grave error of paying too exclusive attention to the environmental factor in disease.

The inadequacy of a perfect system of sanitation to sustain a high level of racial health.—Sanitation is doing much, and will do more, but it will never by itself secure a supremely healthy race. Its disciples assume that disease originates essentially in a faulty environment, and that by a proper regulation of the environment—i.e., by a perfect system of sanitation and by that alone—we can rear a healthy race. This is one of the most grievous fallacies of our time. Never was there a more fatal delusion. We cannot beguile nature with such a bribe; she will not be propitiated by having the environment carefully adapted to, and made easy for, each individual. The whole history of biological evolution is one long story of the *adaptation of the individual to the environment* by a ceaseless and rigorous elimination of the unfit; and it is in this way and this way only that a high racial efficiency can be sustained among men or any other living things. The hygienists are seeking, but they will ever seek in vain, to elude the inexorable law. Were the human species perfectly stable, showing no tendency to vary from generation to generation, their dream might be realised, but no species is, or ever can be, stereotyped. Individual members of it are constantly varying, many of them falling short of the standard of excellence. No two organisms, indeed, are born exactly alike. Taking all the children of a family, and striking their mean standard of fitness, we find that some surpass, while others fall short of this standard, and it is quite impossible to prevent racial deterioration unless those who fall far short are eliminated (as in the ordinary course of nature they would be), because by the law of heredity all natural variations tend to be inherited, and if the unfit are not eliminated their number must increase from generation to generation. I here refer to general fitness, but my proposition applies to each and every character of the individual. To take an example: "A high *racial* (I use this term as distinguished from *individual*) excellence in respect of visual accommodation can only be maintained by a stringent elimination of those displaying errors of refraction. In civilised communities such are not eliminated, and consequently the race is deteriorating in respect of eyesight. In this instance the defect is remediable and the loss is in the main an æsthetic one, but countless other instances could be mentioned in which defective elimination is lowering the efficiency of our race, and in consequence we have among us a vast multitude of the unfit. As a physician I am seeing every day of my life people whom I am compelled to class among nature's failures—people who fall short of the standard which makes life worth living, people who in virtue of their unfitness suffer more than they enjoy. When, therefore, I see, and share in, the vain struggle to patch up such failures and when I read elaborate systems on treatment, I ask myself: Why not look facts sternly in the

face and strike at the root of the evil by conforming to the supreme and inexorable law?"[7] Nothing is more certain than that it is only by a ceaseless and vigilant weeding-out of the unfit variations (which even under the most perfect system of hygiene must necessarily be born) that a high standard of racial excellence can be obtained.

Strange, indeed, it seems that this stern elemental truth has not been recognised by the pathologist. The explanation lies, I believe, in the fact that, all too intent upon his microscope and test-tubes, he has lost sight of the terrible potency of heredity. But recognising it, as we now, I will suppose, do, how, let us ask ourselves, shall we give full play to that searching process of elimination which alone can sustain a high level of racial fitness? Let me, in answer, repeat what I have already said in another place: "Nature's method of elimination is a merciless one; she unceremoniously sacrifices the individual for the benefit of the race—'so careful of the type is she, so careless of the single life.' The sole object of individual elimination, racially considered, is to prevent the unfit individual from leaving offspring to inherit his unfitness, and Nature in her rough-and-ready way achieves this object by simply wiping him out of existence. The same end can be attained, however, by the unfit abstaining from getting offspring and choosing to join the ever-increasing army of the non-marrying. Elimination from the racial standpoint means not having offspring, and all who do not leave offspring are racially eliminated—unrepresented in posterity."[8]

OUTBREAK OF TYPHUS FEVER IN MANCHESTER.

BY HAROLD COATES, M.D., CH.B. VICT., D.P.H.,
SENIOR ASSISTANT TO THE MEDICAL OFFICER OF HEALTH FOR MANCHESTER.

HAVING been engaged with Dr. James Niven in dealing with cases of typhus fever which have occurred in Manchester, I beg to forward you the following brief account of the outbreak.

On Jan. 8th the medical officer of health of Manchester was informed that several of the women employed at a rag-sorting establishment had been attacked by some disease about the nature of which there was some doubt. These cases were first reported as cases of enteric fever, but they all gave a negative reaction with Widal's test. On inquiry it was found that of 14 girls and women who were employed in a particular room in this rag-sorting establishment seven, together with an office-boy who was constantly going to and fro in the room, had been attacked by the disease. These women were employed in sorting clean woollen "tailors' clippings" which are collected from various tailors' shops, chiefly in Manchester, but to some extent from other towns. This rag-sorting establishment is a small place containing two rooms which communicate with each other. All the persons attacked were employed in the smaller room where woollen rags are sorted, while not one was attacked in the larger room where only cotton rags are sorted. Both the cotton and woollen rags are quite clean and new, coming only from tailors' and clothiers' establishments and from warehouses. None of them are dirty rags such as are seen in the places of marine-store dealers. It was found that all these persons began to be ill between Dec. 20th and Dec. 24th, 1900, and when the medical officer of health was informed of the outbreak two patients had died, one was moribund, and the rest were convalescent. We were, therefore, under considerable disadvantages in making a diagnosis.

The following were the principal features of the illness in these eight patients:—The onset was sudden, the illness commencing with severe headache, pain in the back and limbs, chills, and in one or two cases, vomiting. The patients were very ill within two or three days of the onset of the disease. In four of the cases deafness came on about the ninth to the eleventh day. In three of the cases a rash described as having been of a "measly" character had been observed in the wrists, arms, chest, and face, coming on in one case on the seventh day, in another case on the fifth day, and in the third case at a period not defined. Three of the eight patients died. In the others the illness terminated by crisis—in one case on the twelfth day, in three cases on the thirteenth day, and in one case on the sixteenth day. A provisional diagnosis of typhus fever was made and subsequent events proved this to be correct.

One of the patients (Kate C——) had been lodging with Mrs. F——, and 10 days after the onset of Kate C——'s illness Mrs. F—— began to be ill and was removed to Monsall and the typical typhus eruption was observed. One of the cases removed to Monsall, but not seen by us on Jan. 5th, we found on the 20th to have presented a distinct typhus eruption. Another patient (Maggie G——) whose illness commenced on Dec. 31st, 1900, was on Jan. 2nd, 1901, admitted into a general hospital. She was removed to the Fever Hospital as soon as the outbreak was discovered and the patient could be traced, but in the meantime she had infected a nurse, on whom also the typical eruption was seen. This girl also infected her father, mother, and two younger children. The disease ran a typical course in these cases. Two children living next door were also infected by Maggie G——. Another of the girls from the workshop (Mary McL——) infected her mother and brother and two sisters. We were able to see these secondary cases at an early stage, to follow the course of the disease, and thus to place the diagnosis beyond doubt. In the course of the investigations we have learned that other girls, working under the same firm but in another warehouse, left off work on account of illness about Christmas. These girls, however, were not notified to the health office as suffering from infectious disease. Subsequently cases have occurred in each house, one of the girls having infected five persons and the other girl three persons. In the Ancoats district, where the workplace is situated and where these girls work, five other cases in one family have arisen in which no direct connexion with these rag stores has so far been traced. Up to Jan. 10th there have been 28 cases connected with this rag-sorting establishment, and five cases occurring in the neighbourhood in which the source of infection is not as yet known, giving 33 cases, the patients in eight of which have died.

On Feb. 1st, a case of typhus fever was notified in another part of the city and found to be a typical case of typhus fever. In connexion with this case a remarkable history has been obtained. It has been traced through a direct succession of cases right back to the beginning of June, 1900. One of the cases, which commenced on July 19th, was at the time diagnosed as typhus fever. Investigations made at the time failed to reveal the origin of the disease, nor did any subsequent cases come to the knowledge of the medical officer of health. There is, however, no doubt now about the diagnosis in the series of cases extending from June, 1900, to February, 1901, of which the above was one, since different observers—the medical officer of health, Dr. E. S. Reynolds, Dr. Marsden, and a medical attendant on some of the cases—had either diagnosed typhus fever or entertained a strong suspicion of it in one or other of the cases. The temperature charts taken in some instances at the workhouse hospital are also typical. In some of these cases, which occurred about July, August, and September, 1900, the patients were rag-sorters. None, however, worked at the place where the sudden outbreak occurred in December. These women were, however, acquainted, and possibly intervening cases connecting the two outbreaks will come to light. At the present moment, however, the sudden outbreak in December is not clearly accounted for. The total number of cases so far ascertained is as follows: (*a*) cases connected with the outbreak among rag-sorters in December, 1900, 33; (*b*) cases traced from June, 1900, to Feb. 1st, 1901, 18; (*c*) a probable case traced, one; (*d*) a case reported as probably typhus and removed to Monsall, one—a total of 53 cases. In addition there have been seven cases reported in which there is considerable doubt as to the diagnosis.

The following is a brief summary of the administrative measures carried out:—All persons who have been attacked have been removed to the Infectious Diseases Hospital, and the houses which they occupied and their clothing have been disinfected. An effort has been made to induce persons who have been in contact with these patients to undergo a fortnight's isolation for observation in a building specially set aside for the purpose. 24 persons are, or have been, under observation in this manner. A house-to-house inspection has been made in the

[7] Campbell: Monogamy in its Relations to Longevity and the Diseases of Late Life, THE LANCET, June 9th, 1900, p. 1654.
[8] Loc. cit.

neighbourhood of all the infected houses with a view of discovering cases of illness. Every house found in a dirty condition has been disinfected. Fortunately, none of the rags which had been sorted in the department where the outbreak occurred had been sent away. We were thus able to disinfect the whole of the rags which could have been infected by these girls and women. The workshop also was disinfected. All persons who have been in contact and who are not undergoing quarantine are being kept under observation at their homes.

A CONSTANT WATER-SUPPLY AND THE LONDON SANITARY AUTHORITIES.

OVER 50 years ago the City of London Commissioners of Sewers received from "their faithful and obedient humble servant, John Simon" (now Sir John Simon, K.C.B., D.C.L., LL.D.), a report[1] on the sanitary condition of the City, to which he was officer of health. The report dealt with questions of drainage, which that year for the first time was under municipal control, with offensive trades, with intramural burial, with unhealthy houses, with the social condition of the poor, and with water-supply. At the present time cesspools in London have ceased to exist, house drainage is universal, offensive trades are placed under strict supervision, intramural burial has been abolished except at St. Paul's Cathedral and Westminster Abbey, large blocks of insanitary houses have been removed, and the social conditions of the poor have greatly improved. Much that is said on these subjects would if stated now be looked upon as platitude—so greatly has the level of sanitary requirements been raised and universally accepted. The water-supply of the City has also been very greatly improved, yet the remarks made 50 years ago with regard to the City to some extent apply to parts of Water London which are still without a constant supply.

"I am sure that I do not exaggerate the sanitary importance of water," wrote Mr. Simon, in the first paragraph of his report on water-supply, "when I affirm that its unrestricted supply is the first essential of decency, of comfort, and of health; that no civilisation of the poorer classes can exist without it; and that any limitation to its use in the metropolis is a barrier which must maintain thousands in a state of the most unwholesome filth and degradation." No one will be found to disagree with Sir John Simon's dictum. When water is constantly supplied it can be drawn as it is required, and there is no reason why it should be stored in a house. When the supply is not constant storage becomes necessary. On the comparative merits of these two systems the report from which we have already quoted contains a decided expression of opinion. The words are as follows: "I consider the system of intermittent water-supply to be radically bad, not only because it is a system of stint in what ought to be lavishly bestowed, but also because of the necessity which it creates that large and extensive receptacles should be provided, and because of the liability to contamination incurred by water which has to be retained often during a considerable period." We are quite aware that many sanitary authorities have spoken in favour of cisterns, but this was in the belief that the water companies might break down, so that storage at home was necessary. If the water companies supply water unfailingly there can be no need for cisterns.

Lord Llandaff's Commission have lately heard evidence given in favour of the rehabilitation of the water cistern by Sir William Knight, chairman of the Southwark and Vauxhall Water Company and a gentleman who has held the position of Lord Mayor of London. The Commissioners had also brought to their notice an ingenious cistern which was constructed so that a deposit in it was practically unknown, because the bottom of it was so arranged that the water consumer drank the sediment daily, as it was made, a method which rendered any considerable deposit a matter of impossibility. Some years ago, when cisterns were universal, or at any rate common, in the East-end, it was found in one case that the receptacle was used as a bath as well as for the storage of water. The house was let out in tenements and the cistern supplying a family on one floor was situated in a room hired by another family which occupied a room on a higher floor, where it was conveniently placed for washing the children. Lord Llandaff's Commission had amongst other interesting exhibits the opportunity of seeing a vessel containing dead mice and mud which it was stated had been removed from an East-end cistern. In dealing with similar pollutions Mr. Simon went into great detail as to the contamination of cisterns in the City 50 years ago and he remarked: "Everyone who is personally familiar with the working of this system of intermittent supply, can testify to its inconvenience; and though its evils press with immeasurably greater severity on the poor than on the rich, yet the latter are by no means without experience on the subject." In summing up the essential conditions of a good water-supply he insists "that there should always and uninterruptedly be a sufficiency of water to fulfil all reasonable requirements of the population."

Theoretically, Parliament soon became convinced that a constant supply was necessary. Practical expression was given to this opinion by the Metropolis Water Act of 1852 (15 & 16 Vict. cap. 84).

Section XV. of this Act provided that after the expiration of five years from that date every company, subject to the provisions of the special Act relating to the company, should provide and keep in the district mains already laid down or hereafter to be laid down by them *a constant supply of pure and wholesome water* sufficient for the domestic use of the inhabitants of all houses supplied by the company at such pressure as would make the water reach the top storey of the highest of such houses, but not exceeding the level prescribed by the special Act of such company,[2] but it was provided that no company should be bound to provide a constant supply of water to any district main until four-fifths of the owners or occupiers of the houses on such main should in writing under their hands require the company to provide such supply, nor even upon such requisition, in case it could be shown by the company objecting to the alteration that more than one-fifth of the houses on such main were not supplied with suitable water fittings, constructed according to the regulations prescribed either by an Act of Parliament or made by the company with the approval of the Board of Trade; and after any such requisition for a constant supply should be delivered to the company it should be lawful for a surveyor, acting under the authority of the company, between certain specified hours, to enter into any house which would be affected by the alteration, in order to ascertain whether the water fittings in the house conformed with the regulations; and it was further provided that any company might, with the consent of the Board of Trade, suspend the giving of a constant supply, or give it in succession to the several districts of the company or any parts of such districts as might be found to be convenient; and the company were allowed, after due notice, to abstain from supplying or to cut off the communication pipes and withdraw the supply of water from any house in which the water apparatus was not in conformity with the regulations.

It will be readily seen that rather cumbrous proceedings were necessary to enforce the working of the provisions of this Act, and the result was that they were not used, and as a matter of fact no requisition for constant supply was ever made under the Metropolis Water Act of 1852. A Parliamentary Committee which was appointed in the year 1871 to report on the Metropolis Water Bill introduced that year pointed out that a written requisition of four-fifths of the inhabitants of a clearly defined area could not be easily obtained even for a good object, but that was not the only difficulty in this particular case, because the term "district main" in the Act of 1852 had no clear and definite meaning, and therefore the terms of the requisition rendered the provision "wholly nugatory." Evidently those who framed the Act were more to blame in the matter than the unfortunate water consumers.

Between the years 1852 and 1871 questions concerning water-supply frequently engaged the attention of Parliament. A report of the Royal Commission on the Prevention of the Pollution of Rivers appeared in the year 1866, and ultimately led to legislation. The outbreak of cholera which was traced to the water distributed by the East London Company led to the introduction of Bills by that company and these were reported on by a committee of the House of Commons in the year 1867. Two years later a Royal Commission issued a report on water-supply. These reports and other evidence led the Parliamentary Committee in 1871 to insist on the advantages of a system of constant supply, and in consequence of their advice the Metropolis Water Act of that year was passed. Under the provisions of this Act the matter was placed in the hands of various metropolitan authorities—for the City their Corporation, for other parts of

[1] Report on the Sanitary Condition of the City of London for the year 848, by John Simon, F.R.S. The report is dated Nov. 6th, 1849.

[2] The Kent Waterworks and the Hampstead Waterworks Company (a business afterwards acquired by the New River Company) were not required to give a supply at any height exceeding 180 feet above Trinity high-water mark, nor the East London Water Company to any height exceeding 40 feet above the level of the pavement nearest the point at which such supply should be required

the metropolis the Metropolitan Board of Works, and for other places the commissioners, local boards, or vestries. The sections of the Act which apply to constant service are Sections 7 and 8.

Under Section 7 every company might, and from and after the expiration of eight months from the passing of the Act every company was compelled, when required so to do, in the manner directed by the Act, to provide and keep throughout their water limits a constant supply of pure and wholesome water sufficient for the domestic purposes of the inhabitants within those limits constantly laid on at such pressure as would make it reach the top storey of the highest houses within the area (but not exceeding the level prescribed by the special Act of each company), and every such company was required, subject to the provisions of the special Act as the same are amended by the Act, to give the inhabitants of the area a constant supply for domestic purposes in the manner prescribed. Section 8 provided that at any time after the expiration of six months from the passing of the Act the metropolitan authority should, whenever they were of opinion that there should be in any district a constant supply, make application to the company within the water limits in which the district is situated, requiring a constant supply in the district, and any company might without any such application propose to the metropolitan authority to give a constant supply in any district.

Sections 26, 27, and 28 dealt with the provision and regulation of the fittings necessitated by water supplied on the constant system and for the publication in the *London Gazette* of notices of the alteration in the system of supply.

In the year 1897 a Metropolis Water Act was passed (60 & 61 Vict. cap. 55) and fresh regulations were made to ensure that continuous supply should be given by the water companies. Under the provisions of this Act any consumer or any local authority was empowered to bring before the Railway and Canal Commissioners any complaint as to the quantity and quality of water supplied or their failure to perform any statutory duty. The Railway and Canal Commissioners were empowered to impose penalties and to direct the removal of the cause of complaint. Water consumers were allowed to have (if they could get it) the assistance of the local authorities in obtaining the determination of any question of general interest in reference to the quantity and quality of the water supplied or the charges made by the companies. The local authorities were authorised to become parties to the legal proceedings and to make themselves liable for costs. Lord Llandaff's Commission in their report say they have been struck by repeated instances of ignorance or neglect on the part of the local authorities and of the water consumers for whose benefit these enactments were made. The local authorities which are empowered under the provisions of the Metropolis Water Act of 1897 to assist any water consumer who may feel himself aggrieved are the council of any county, borough, or district, for the City the Corporation of London, and any vestry, district board, or local board of health in the county of London, each authority having such power in the district in which the aggrieved water consumer is living. Under the provisions of the London Government Act, 1899 (62 & 63 Vict. cap. 14) the metropolitan boroughs have been entrusted with the powers and duties formerly possessed by the vestries in regard to the water-supply. In the interests of the people of London it is to be hoped that they will exercise their power to ensure a constant service of water throughout the whole of London. When there is a constant water-supply cisterns are not only unnecessary and useless, they are harmful, inasmuch as they introduce the possibilities of contamination of the stored water

Enough, we hope, has been said to show that the new regulations which the metropolitan water companies wish to impose on the people of London ought not to be legalised.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Karl Haegler, *privat-docent* of Surgery, and Dr. Friedrich Egger, *privat-docent* of Medicine, have been appointed Extraordinary Professors.—*Berlin:* Dr. Georg Wetzel has been recognised as *privat-docent* of Anatomy, Dr. Felix Klemperer as *privat-docent* of Medicine, and Dr. Karl Bruhns as *privat-docent* of Dermatology.—*Copenhagen* Dr. J. Fibiger has been appointed to the chair of Pathological Anatomy in succession to the late Dr. Lange.—*Kiel:* Dr. Theodor Kirchhoff, *privat-docent* of Psychiatry, has been granted the title of Professor.—*Leipsic:* Dr. Richard Burian has been recognised as *privat-docent* of Physiology. A new dermatological clinic has been opened; it is replete with apparatus for Roentgen rays, for urethroscopy, cystoscopy, and the Finsen light treatment, and it is under the charge of Professor G. Riehl.

THE WAR IN SOUTH AFRICA.

FROM a medical point of view the most striking news from South Africa is the appearance of plague at the Cape. The first cases occurred at the Cape Town docks. The outbreak has so far been of a very limited extent, but the two important points connected with it are the appearance of some disease among the rats giving rise to their wholesale migration, and the spread of the infection as indicated by the occurrence of some cases of plague at other places than the docks. It was noticed that the rats at the south arm of the docks, where the military transports discharge, were making an exodus and migrating to the military camp at Greenpoint at which place they soon commenced to swarm. We have said the alleged occurrence of plague because Dr. Edington, the Government bacteriologist, maintains that the disease from which the city rats are suffering is not bubonic plague. On the other hand, medical opinion at the Cape declares that there can be little or no doubt as to the identity of the disease with bubonic plague in the patients under treatment, and stringent measures have been, or are being, taken on that assumption with the view of preventing its spread. The local Government and the civil and military authorities and colonial medical officer of health at Cape Town are acting in concert and a crusade is in progress against rats. Cape Town is below the standard of what it should be according to our present ideas of sanitation. The district where some of the cases have occurred is densely populated by Kaffirs and coloured people. The disease is mainly confined to the Kaffirs, but a few cases have occurred in widely separated parts of the city and one European has been attacked. The existence of plague has, we believe, been officially admitted. It cannot be denied that this is a serious and embarrassing occurrence, but it does not at all follow that, if it be veritably and indeed bubonic plague, it should assume epidemic proportions. Among the principal measures required to be taken are, the prompt isolation of the infected, the introduction of a system of plague inoculation, the wholesale destruction of rats, the evacuation of infected houses and sites, the provision of suitable camping grounds and camps, and, as far as practicable, the application of those sanitary and hygienic measures which have been found generally useful and efficacious in dealing with epidemic diseases of any kind. There is no more practical and effective measure that a change of site under such circumstances.

As regards the South African war news, it may be said that after a period of inaction the war is being prosecuted with energy and with results which, so far as they go, may be regarded as favourable to the British forces. It is evident that Lord Kitchener's movements have been, and still are, much hampered by the want of more mounted troops to follow up any defeats of the Boer forces by actively pursuing then when in retreat, capturing their convoys, and compelling them to surrender. As Lord Roberts has explained in his despatches, he was fully aware when he undertook and successfully carried out his rapid plan of campaign that he was compelled to set aside the ordinary rules of war and accept all the risks to which his strategy laid him open. Although the object was attained and the military precautions usually adopted were set aside in order to do this, it did not follow that the risks were overcome or removed. The tactics of the Boer leaders at the present time are to take any advantage, to surprise and attack isolated posts and lines of communication wherever possible, and thus to prolong the war in the hope of "something turning up." But time is nevertheless fighting against them and when large reinforcements of mounted troops have arrived Lord Kitchener will, it is to be hoped, be in a position to carry on his present system of warfare with redoubled vigour. That the Boers are now fighting with something very like desperation may be inferred from the large numbers of killed on both sides as compared with wounded which have characterised many of their late engagements.

In addition to the list of casualties attributable to the recent fighting in various directions we regret to notice that the lists of the sick and dead from enteric fever and other diseases continue to be lengthy ones.

THE LANCET RELIEF FUND.

TWELFTH ANNUAL REPORT OF THE ALMONERS.

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians of London (Sir WILLIAM SELBY CHURCH, Bart., M.D. Oxon), the President of the Royal College of Surgeons of England (Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., F.R.C.S. Eng., F.R.C.S. Irel., M.Ch.), the President of the General Medical Council (Sir WILLIAM TURNER, K.C.B., M.B. Lond., F.R.C.S. Eng. and Edin., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the twelfth annual report the Almoners think it well again to direct attention to the object for which the Fund was established.

The Fund is sustained solely by the Proprietors of THE LANCET who provide every January the sum of at least £300 and is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners or to the widows and orphans of members of the profession in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established; and as a result the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb. 16th, 1889, in the following words:—

> We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief.

And who, it may once more be pointed out, are likely to be permanently benefited thereby.

The balance in hand at the end of 1899 amounted to the sum of £358 1*s.* 6*d.* On Jan. 1st, 1900, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. The sum of £305 has been granted in relief either by way of loan or of gift, leaving a balance of £352 17*s.* 4*d.* as per Statement of Accounts.

There have been considered altogether during the 12 months ending Dec. 31st, 1900, 42 applications for relief (the number the previous year having been 33). In 34 cases assistance was awarded either as a loan or as a gift, according to the request of the applicant, the amount of the grants ranging this year from £5 to £20.

The Almoners are glad to find from the letters received from recipients of the Fund that it continues to be of service to unfortunate members of the profession and that the particular object of assisting cases of emergency and immediate distress has been attained. (Signed)

WILLIAM MAC CORMAC (Chairman). WM. TURNER. W. S. CHURCH. THOMAS WAKLEY. THOMAS WAKLEY, Junr.

I find by the Bankers' Book that the actual balance on Jan. 1st, 1900, to the credit of the Fund was £358 1*s.* 6*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st, 1900.

The balance at the Bank on Dec. 31st, 1900, was the sum of £352 17*s.* 4*d.* I have also checked the receipts for disbursements and find the above account strictly accurate

January 25th, 1901.

HENRY A. PITMAN, Hon. Auditor

ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

II.[1]

WE now come to that portion of Mr. Shirley Murphy's report which deals with the prevalence and fatality of the commoner forms of infectious disease. For the last two years London has been practically free from small-pox, only 29 cases having been notified in the year 1899 and 33 cases in the preceding year. The London death-rate from small-pox has been scarcely appreciable since the year 1895 and throughout the 10 years 1889–98 it has been below the rate of Paris, Brussels, St. Petersburg, Vienna, Rome, and New York. The fortunate immunity of London from serious invasion by small-pox is, however, to be attributed solely to the promptitude with which the earliest cases have been recognised and isolated. Had it been otherwise the cases freshly imported from time to time, few though they have been, would inevitably have caused a general prevalence of small-pox long before the present time, especially in a community like our own which is so largely composed of unvaccinated children. Having regard to the serious epidemic of small-pox now existing in Glasgow, between which city and the metropolis intercommunication is constant, prudent parents will give heed to Mr. Shirley Murphy's solemn warning, which is to the effect that ever since the appointment of the Royal Commission on vaccination the proportion of unvaccinated children in London has steadily increased year after year. The figures for years subsequent to 1897 are not as yet available, but in that year we learn that the proportion of children not finally accounted for as regards vaccination amounted to 29·1 per cent. of the total births. It may therefore safely be assumed that as the proportion of unvaccinated children has steadily increased during the last decade at least one-third of the children born in London are at the present time suffered to remain unprotected against small-pox.

Judged by the mortality alone London would almost seem to have been freer from scarlet fever in 1899 than in any previous year since the passing of the Notification Act; but on reference to the column showing the number of attacks recorded this appears to be due to the exceptionally low fatality (2·2 per cent.) among the recorded attacks, for the cases of scarlet fever actually notified in 1899 were relatively more numerous than they had been either in the year 1891 or in 1898. The scarlet fever death-rate of London last year was lower than that of any of the other large English towns except Manchester, Birmingham, Bristol, and West Ham, and also lower than that of any of the principal foreign cities except Paris, Brussels, Amsterdam, and Rome. Mr. Shirley Murphy refers yet again in the present report to the occurrence in certain London sanitary districts of "return cases" of scarlet fever —i.e., cases occurring in houses shortly after the return home of a previous case which had been discharged apparently cured from hospital. In Paddington there were nine such cases, in Plumstead 14, in Kensington four, in Fulham 10, and in Stoke Newington three. It appears that in most of these cases the child who had caused the mischief was found on return from hospital to be suffering either from nasal discharge or from enlarged glands. Mr. Shirley Murphy quotes the opinion of the medical officer of health of Stoke Newington to the effect that special provision should be made for the isolation of such cases as the above or at any rate that the medical officer of health should be warned of their return home so that they may be watched. From the present report we learn that "return cases" not infrequently occur in connexion with the convalescent stage of diphtheria also, they are by no means limited to scarlet fever.

Diphtheria was more prevalent in London during 1899 than in the preceding year; the reported cases also exceeded the annual average for 1891–98. The case fatality among the reported attacks was, however, lower last year than in any year since the passing of the Notification Act. Compared with 11 of the largest English towns the London death-rate from diphtheria was higher last year than that of any other except Leeds, Sheffield, and West Ham, whilst it was higher than that of any of the chief foreign cities except Stockholm, St. Petersburg, and New York. The use of antitoxic serum is being encouraged by the sanitary authorities of many of the London districts, some of them charging a fee for the serum, whilst others supply it without charge. Mr. Shirley Murphy states that this provision for the safety of the public is generally appreciated by medical practitioners, who consequently always know where to apply for the serum in case of emergency. In Lambeth the use of antitoxin appears to have been especially satisfactory, for out of 53 cases in that parish thus treated the results were successful in 52. The reduction in the case fatality of diphtheria in recent years is remarkable and highly satisfactory; it is shown graphically in a chart contained in the report. The relative incidence of diphtheria attack upon London children from three to 13 years of age continues to increase from year to year. This is shown in a table which we have not space to reproduce here. Mr. Shirley Murphy adds some useful words of caution with reference to the occurrence of diphtheria attacks in undue proportion among children at school ages. He states his opinion that, irrespective of the general prevalence of this disease, be it great or small, in any locality, a notable increase in the ratio of attacks at school ages should always be taken as the signal for special watchfulness, because such increase may be due to school attendance; and in this way is very likely to be the precursor of a serious outburst of the disease, although there may be no concurrent excess of attacks at other than school ages. Thus, for example, in a particular school cases of diphtheria may occur at intervals far apart from each other in point of time—so far apart, indeed, as to obscure the share the school is taking in spreading the disease. Nevertheless, the succession between the known attacks may be maintained by means of unrecognised cases, although there may exist no abnormal general prevalence of the disease to cause alarm. The disastrous school outbreak at Lewisham in 1896 is quoted as an illustration of the concurrence of a decrease of attacks among the general population with a relative increase among school children, the latter increase culminating in the serious outbreak referred to. We regret to learn that during the last two years the percentage of attacks among school children at Lewisham has again been increasing and that there has been concurrently a serious increase in the number of fresh cases of the disease outside schools in that district. It would therefore appear desirable to inquire, as Mr. Shirley Murphy does inquire very pertinently, whether infection at school was once more responsible for the large prevalence of diphtheria at Lewisham in 1899.

For several years past Mr. Shirley Murphy has commented in considerable detail on the behaviour of typhus fever in the older and poorer parts of the metropolis. Within the memory of many practitioners still living typhus fever was one of the most terrible scourges of certain well-known districts. Even so recently as the year 1869 this disease was responsible for a death-rate of 690 per 1,000,000 of the London population as a whole, and in the denser and more insanitary areas the mortality amounted to many times this figure. Throughout the last decade, however, typhus fever has been attended by but insignificant fatality in London, the deaths in the whole county numbering only two last year and three the year before. The parts of London which have in recent years been associated with the spread of typhus fever are Bermondsey, Rotherhithe, and the neighbouring district of St. George-the-Martyr. The frequent recurrence of typhus fever in this part of London is noteworthy and the history of the cases reported shows how readily the disease may be overlooked, especially in its milder forms. There is much probability that the disease has retained a foothold in these parts through the medium of unrecognised cases. It is well known that the severity of typhus fever varies greatly and the attacks especially amongst children, are often so slight as to amount to little more than mere poorliness. "There is, therefore" says Mr. Shirley Murphy, "no improbability that the disease has been maintained in these districts by persons suffering from so mild a form of typhus that it is impossible to recognise the malady, the cases coming to light being a few of the total number who are suffering from more severe attacks. If natural causes may reduce the severity of disease they

[1] No. I. was published in THE LANCET of Feb. 9th, 1901, p. 421.

may also increase it, and in that event there is no certainty that there will not eventually be much greater prevalence of typhus than has been experienced in late years."

Enteric fever showed greater prevalence in London last year than in any other year since the passing of the Notification Act, the reported cases being in the proportion of 1 in each 1000 of the population. In several instances Mr. Shirley Murphy quotes illustrations of the communication of enteric fever from one person to another. Thus, in the district of Kensington the illness of one person was followed by that of 11 other persons associated with the first sufferer or others infected by him; 10 houses in all were thus invaded. In Fulham a series of six cases was reported, and in St. Pancras a series of nine cases in a family of 11 persons. In yet another district account is given of three similar groups in which the number of persons thus infected from a common source was respectively six, six, and eight. The experience of enteric fever in 1899, as, indeed, in that of previous years, points to the spread of enteric fever infection from previous cases of this disease, the nature of the illness in the first case not having been recognised It further shows the risk of the retention of cases of enteric fever in the houses of poor persons when circumstances do not allow of efficient isolation The early recognition of enteric fever, the use of the Widal test in doubtful cases, the isolation of the sufferer, and the employment of nurses beyond middle life to attend upon the sick are, in Mr. Shirley Murphy's opinion, the precautions which are needed to limit the spread of enteric fever.

We are glad to note that the interesting diagram showing the relation of overcrowding to phthisis mortality—which we noticed for the first time in the report for 1898—has been repeated in the report before us. The diagram shows that in 1899, as in the previous year, the mortality from all causes, from phthisis, and from diseases other than phthisis, increases with overcrowding, and that the maximum increase from diseases other than phthisis occurs somewhat earlier in life than does the maximum increase from that disease itself. Mr. Shirley Murphy's remarks on the relation of the dwelling-house to the production of phthisis are eminently practical and he presses them home very effectively with the help of the diagram before mentioned. In concluding our notice of this excellent report we would especially commend this particular part of it to the study of those who are interested in the success of the outdoor treatment of consumption, feeling confident that it will be found both suggestive and profitable reading.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb. 7th, Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., the President, being in the chair.

The following Address of Condolence was passed and the College seal was affixed:—

THE HUMBLE ADDRESS OF THE PRESIDENT, VICE-PRESIDENTS, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND TO

HIS MOST EXCELLENT MAJESTY EDWARD VII.,
King of Great Britain and Ireland.

MAY IT PLEASE YOUR MAJESTY,—We, the President, Vice-Presidents, and Council of the Royal College of Surgeons of England, venture to approach Your Majesty in order to express our profound grief at the death of Your Majesty's beloved mother, our late revered Sovereign, and we humbly solicit Your Majesty graciously to receive our earnest and respectful sympathy.

We desire to record our heartfelt sorrow at the loss of a Sovereign whose reign has brought unexampled prosperity to the empire and whose dignity of life and unselfish devotion to duty have won the lasting admiration and gratitude of her subjects.

Wise and liberal in her rule and ever solicitous for the welfare and happiness of the nation, Queen Victoria will live in the hearts of her people the symbol of all that is noble and good.

We also desire respectfully to express to Your Majesty our dutiful allegiance and unswerving devotion, and we fervently pray that Your Majesty may long reign in the affections of a loyal, happy, and united people.

In witness whereof, We, Your Majesty's loyal and dutiful subjects, have caused the Common Seal of the College to be hereunto affixed this 7th day of February, 1901.

The PRESIDENT reported that owing to the lamented death of Her Majesty Queen Victoria it had been determined that the dinner arranged in connexion with the Hunterian Festival on Feb. 14th should not take place, but that the Hunterian Oration should be delivered at 4 P.M. on that day in accordance with the terms of the Hunterian Trust.

On the recommendation of the Museum Committee the Council authorised the purchase of two Chinese skeletons and of some Chinese skulls.

The Council passed a vote of thanks to Mr. Alfred Sieveking, of the Uganda Railway Service, for a gift of ethnological specimens from East Africa

Mr. Thomas Bryant was re-appointed as representative of the College on the General Medical Council for a further period of three years.

In response to an invitation from the Chancellor, Council, and Senate of the University of Glasgow, the President, Sir William MacCormac, the Senior Vice-President, Mr. John Langton, and Mr. Mayo Robson were appointed delegates from the College on the occasion of the ninth jubilee celebrations of the University in June next.

The Secretary was authorised to remove from the list of Members published in the College Calendar the names of all Members admitted before the year 1843 whom he may be unable to trace as still living.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6908 births and 4473 deaths were registered during the week ending Feb. 9th. The annual rate of mortality in these towns, which had declined from 19·6 to 16·4 per 1000 in the four preceding weeks, rose again last week to 19·8. In London the death-rate was 18·7 per 1000, while it averaged 20·5 in the 32 large provincial towns. The lowest death-rates in these towns were 12·3 in Cardiff, 12·4 in Croydon, 14·4 in West Ham, and 15·1 in Bolton and in Bradford; the highest rates were 24·7 in Manchester, 27·5 in Salford, 27·9 in Liverpool, and 29·5 in Norwich. The 4473 deaths in these towns included 397 which were referred to the principal zymotic diseases, against 374, 347, and 323 in the three preceding weeks; of these, 129 resulted from whooping-cough, 101 from diphtheria, 57 from measles, 44 from "fever" (principally enteric), 40 from diarrhœal diseases, and 26 from scarlet fever. The lowest death-rates last week from these diseases occurred in Brighton, Swansea, Norwich, Burnley, and Huddersfield; and the highest rates in Nottingham, Birkenhead, Salford, and Blackburn. The greatest mortality from measles occurred in Liverpool; and from whooping-cough in Croydon, Plymouth, Bristol, Nottingham, Birkenhead, and Preston. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 101 deaths from diphtheria included 29 in London, 10 in Sheffield, eight in Leeds, eight in Liverpool, eight in Manchester, seven in Blackburn, and six in Leicester. No fatal case of small-pox was registered in any of the 33 large towns, and only one small-pox patient remained under treatment in the Metropolitan Asylums hospitals on Saturday, Feb. 9th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1963, against numbers declining from 2535 to 2037 on the six preceding Saturdays; 145 new cases were admitted during the week, against 187, 172, and 178 in the three preceding weeks. Influenza was certified as the primary cause of 12 deaths in London last week. The deaths referred to diseases of the respiratory organs in London, which had been 422, 394, and 323 in the three preceding weeks, rose again last week to 397, but were 75 below the corrected average. The causes of 75, or 1·7 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Bristol, Bolton, Oldham, and in eight other smaller towns. The largest proportions of uncertified deaths were registered in Birmingham, Liverpool Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·1 and 22·2 per 1000 in the two preceding weeks, further rose to 23·2 during the week ending Feb. 9th, and showed an excess of 3·4 per 1000

over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·4 in Leith and 20·3 in Dundee to 25 5 in Glasgow and 27·4 in Paisley. The 726 deaths in these towns included 37 which were referred to whooping-cough, 18 to diarrhœa, 14 to measles, 11 to small-pox, 10 to "fever," seven to diphtheria, and six to scarlet fever. In all 103 deaths resulted from these principal zymotic diseases, against 106 and 126 in the two preceding weeks. These 103 deaths were equal to an annual rate of 3·3 per 1000, which was 1·5 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The deaths from whooping-cough, which had been 39 and 43 in the two preceding weeks, declined again to 37 last week, and included 27 in Glasgow, five in Edinburgh, two in Dundee, and two in Greenock The fatal cases of diarrhœa, which had been 15 and 27 in the two preceding weeks, declined again last week to 18, of which eight were registered in Glasgow, three in Dundee, two in Aberdeen, and two in Leith. The deaths from measles, which had been 23, 18, and 16 in the three preceding weeks, further declined to 14 last week, and included six in Edinburgh and six in Aberdeen. The deaths from small-pox, which had been three, 11, and 24 in the three preceding weeks, declined again to 11 last week, and included 10 in Glasgow and one in Paisley. The fatal cases of "fever," which had been 15 and six in the two preceding weeks, rose again last week to 10, of which nine were recorded in Glasgow. The deaths from diphtheria, which had been eight and seven in the two preceding weeks, were again seven last week, and included two in Glasgow, two in Edinburgh, and two in Dundee. The six fatal cases of scarlet fever showed an excess of three over the number in the preceding week and included four in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 145 and 123 in the two preceding weeks, rose again last week to 158, but were 84 below the number in the corresponding period of last year. The causes of 37, or more than 5 per cent., of the deaths in these eight towns last week were not certified

---

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·4, 28·2, and 27·4 per 1000 in the three preceding weeks, rose again to 34·0 during the week ending Feb. 9th During the past four weeks the death-rate in the city has averaged 30·0 per 1000, the rates during the same period being 17·8 in London and 21·2 in Edinburgh The 226 deaths belonging to Dublin registered during the week under notice were 44 in excess of the number in the preceding week, and included 16 which were referred to the principal zymotic diseases, against 20 and 18 in the two preceding weeks; of these, nine resulted from whooping-cough, five from 'fever," and two from diarrhœa These 16 deaths were equal to an annual rate of 2·4 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·5 in Edinburgh The fatal cases of whooping-cough, which had been eight and 12 in the two preceding weeks, declined again last week to nine. The deaths referred to different forms of "fever," which had been six and three in the two preceding weeks, rose again to five during the week under notice. The 226 deaths in Dublin last week included 37 of children under one year of age and 61 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a marked excess over the numbers recorded in the preceding week. Eight inquest cases and six deaths from violence were registered, and 70, or nearly one-third, of the deaths occurred in public institutions. The causes of 15, or nearly 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 29 boroughs and cities in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·2 per 1000 of the population, estimated at 4,651,113 persons in the middle of the year. In the three preceding months the rates had been 10·7, 10·0, and 8·0 per 1000 respectively. The rates were considerably below the average in Kensington, Westminster, St. Marylebone, City of London, and Wandsworth; while they showed the largest excess in Hammersmith, Fulham, Bethnal Green, Poplar, and Deptford. Four cases of small-pox were notified last month, of which one occurred in Kensington, one in Hampstead, one in Stepney, and one in Poplar. Four small-pox patients were admitted into the Metropolitan Asylums hospitals during the month, and three remained under treatment on Saturday, Feb. 2nd. Scarlet fever was considerably less prevalent than it had been during the four preceding months; among the various metropolitan boroughs this disease showed the greatest proportional prevalence in Hammersmith, Fulham, Stoke Newington, Deptford, and Lewisham The Metropolitan Asylums hospitals contained 1979 scarlet fever patients at the end of January, against 2569, 2659, and 2460 at the end of the three preceding months; the weekly admissions averaged 164, against 314, 259, and 214 in the three preceding months. The prevalence of diphtheria also showed a marked decline as compared with that recorded in recent months; the greatest proportional prevalence of this disease occurred in Hammersmith, Fulham, Bethnal Green, Poplar, and Deptford. There were 1113 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1458, 1524, and 1343 at the end of the three preceding months; the weekly admissions averaged 129, against 206, 185, and 157 in the three preceding months. The prevalence of enteric fever last month showed a continued decrease from that recorded in each of the two preceding months; among the various metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, Chelsea, City of London, Bethnal Green, Stepney, and Bermondsey. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 444, 436, and 403 at the end of the three preceding months, had further declined to 299 at the end of January; the weekly admissions averaged 32, against 61, 61, and 51 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Holborn, Shoreditch, Bethnal Green, and Deptford boroughs. The 38 cases of puerperal fever included six in Islington, six in Camberwell, and three in Hampstead.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the patients had previously resided. During the five weeks ending Feb. 2nd, the deaths of 7796 persons belonging to London were registered, equal to an annual rate of 17·5 per 1000, against 15·3, 16·8, and 16·2 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 12·4 in Hampstead, 13·1 in Stoke Newington, 13 4 in Wandsworth, 14·5 in Hackney, and 14·7 in Battersea; the highest rates were 21·7 in Finsbury, 22·3 in Bermondsey, 22·8 in Southwark, 23 2 in Bethnal Green, and 24 9 in City of London. During the five weeks of January 632 deaths were referred to the principal zymotic diseases; of these, 140 resulted from measles, 43 from scarlet fever, 127 from diphtheria, 180 from whooping-cough, one from typhus, 74 from enteric fever, and 67 from diarrhœa. The lowest death-rates last month from these diseases occurred in City of Westminster, St. Marylebone, Hampstead, Stoke Newington, Lambeth, Battersea, and Woolwich; and the highest rates in Hammersmith, Fulham, Bethnal Green, Southwark, Bermondsey, and Greenwich boroughs. The 140 deaths from measles showed a decline of 119 from the corrected average number; this disease was proportionally most fatal in Bethnal Green, Southwark, Bermondsey, Camberwell, and Greenwich. The 43 fatal cases of scarlet fever were less than one-half of the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Fulham, St. Pancras, Bermondsey, Camberwell, and Lewisham. The 127 deaths from diphtheria were 99 below the corrected average; this disease showed the greatest proportional fatality in Hammersmith, Fulham, Stoke Newington, Bethnal Green, and Poplar. The 180 fatal cases of whooping-cough were 137 less than the average in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Shoreditch, Bethnal Green, Southwark, Bermondsey, and Greenwich. The 74 deaths from "fever" showed an excess of 14 over the corrected

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1901.

* Including 26 cases of membranous croup.

† Including deaths from membranous croup.

average; the highest proportional mortality from "fever" occurred in Hammersmith, Chelsea, St. Pancras, Holborn, Finsbury, and City of London boroughs. The 67 fatal cases of diarrhœa were equal to the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Holborn, Bethnal Green, Deptford, and Lewisham. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during January was more than 35 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 121 per 1000. The lowest rates of infant mortality were recorded in Chelsea, Stoke Newington, Hackney, Wandsworth, and Greenwich; and the highest rates in Kensington, Fulham, City of London, Shoreditch, and Bethnal Green.

THE SERVICES.

THE VICTORIA CROSS.

THE *London Gazette* of Feb. 12th announces that Lieutenant W. H. S. Nickerson, R.A.M.C., attached to Mounted Infantry, has been awarded the decoration of the Victoria Cross for the following act of courage:—

At Wakkerstroom, on the evening of April 20th, 1900, during the advance of the infantry to support the mounted troops, Lieutenant Nickerson went, in the most gallant manner, under a heavy rifle and shell fire, to attend a wounded man, dressed his wounds, and remained with him till he had him conveyed to a place of safety.

MENTIONED IN DESPATCHES.

In the South African despatches which have now been presented to both Houses of Parliament the following comments are made and names mentioned for gallantry or conspicuous services:—

From Lord Roberts to the Secretary of State for War, dated March 31st, 1900:—

Surgeon-General W. D. Wilson, M.B., has had responsible and important duties to perform. The arrangements necessary to provide for the wants of the many sick and wounded in South Africa have required unremitting care and forethought, and the successful way in which they have been carried out reflects the greatest credit on him.

Colonel W. F. Stevenson, M.B., R.A.M.C., has been principal medical officer with the force, and I desire to draw attention not only to the efficient manner in which he has supervised the working of the Corps but also to the assistance I have received from him at all times. I cannot speak too highly of the care and devotion shown by the medical officers to the sick and wounded, or of the gallant way in which many of them have exposed themselves when performing their duties on the field of battle.

Mr. Watson Cheyne, M.B., F.R.S., and Mr. Kendal Franks, M.B., F.R.C.S.I., consulting surgeons, who have accompanied the army, have rendered invaluable service by their advice and assistance to the medical officers. They have been unwearying in their work among the wounded and sick, and, humanly speaking, many a valuable life has been saved by their skill.

Major J. H. Fiaschi, New South Wales Medical Staff Corps, is deserving of special mention on account of the assistance which he rendered to the sick and wounded, as well as upon the efficient condition in which he has kept the ambulance under his command, the services of which, ever since its arrival, have been most valuable.

Lieutenant-Colonel W. R. Donovan, R.A.M.C., principal medical officer of the Cavalry Divisional Staff and Troops.

Cape Medical Bearer Company.—Captain J. J. Brownlee and Serjeant A. Bettington.

Bearer Company, Royal Army Medical Corps.—Major R. H. S. Sawyer and Captain P. J. Probyn.

Major-General Baden Powell's despatches to Lord Roberts, dated May 18th, 1900, referring to the siege of Mafeking:—

Major Anderson, Royal Army Medical Corps, throughout the siege showed untiring zeal, coupled with coolness and gallantry in attending the wounded under fire in action, in addition to his eminent professional ability. Latterly, as principal medical officer, his unfailing tact and administrative capabilities rendered his services of greatest value. The strain of his devotion to his duty told heavily on his health.

Medical Staff.—Dr. W. Hayes, Surgeon Major Holmden, British South Africa Police, and Dr. T. Hayes. All worked with conspicuous zeal and skill under a never-ending strain of work; all of them very frequently under fire in carrying out their duties, even in their own hospital.

From Sir Charles Warren to Lord Roberts, dated June 29th, 1900, describing the action in the vicinity of Fabers Put on May 30th:—

The main farmhouse was rapidly cleared out and turned into a hospital under the directions of the senior medical officer. All the medical arrangements were most satisfactory, the following officers having done very excellent work, not only in the hospital, but also in the field dressing the wounds under heavy fire—viz.: Major McLaughlin senior medical officer; Major Cox, officer commanding Cape Field Hospital; Major Worthington, attached Canadian Artillery; and Captain C. Smith, attached 8th Battalion Imperial Yeomanry.

From Sir George White to the Secretary of State for War, dated Ladysmith, Dec. 2nd, 1899:—

I also desire to bring to your notice the following ..... have rendered excellent services: ..... Lieutenant-Colonel R. W. Mapleton, R.A.M.C.

Royal Army Medical Corps.—Lieutenant-Colonel P. H. Johnston, Major H. Martin, Major M. W. Kerin, and Captain G. S. Walker.

From Sir George White, dated Cape Town, March 23rd, 1900:—

Colonel R. Exham, Royal Army Medical Corps, did all that a principal medical officer could do in organising the medical services under circumstances of exceptional difficulty, and with *personnel* and *materiel* both inadequate for a siege of such long duration, accompanied by such a great amount of sickness.

Lieutenant-Colonel R. W. Mapleton, Royal Army Medical Corps, in charge of Intombi Hospital Camp, was placed in a most exceptional position, in charge of a neutral camp where the maintenance of discipline in the ordinary way was impossible, but in the face of all difficulties he did everything possible to maintain the sanitation of the camp, and to ensure the well-being of the sick and wounded.

Major F. H. Treherne, Royal Army Medical Corps; Major J. F. Bateson, Royal Army Medical Corps.

Royal Army Medical Corps.—Lieutenant-Colonel S. H. Carter, Major H. Martin, Major R. L. Love, Major M. W. Kerin, Major S. Westcott, Major D. Bruce, and Captain G. S. Walker (died of enteric fever, Feb 23rd, 1901).

Natal Volunteer Medical Staff.—Captain H. T. Platt.

Indian Subordinate Medical Department. — 1st Class Assistant-Surgeon J. Moore, 1st Class Assistant Surgeon J. B. Farrell, 1st Class Assistant-Surgeon A. D. McIntyre, 2nd Class Assistant-Surgeon E. St. Romaine, and 2nd Class Assistant Surgeon V. V. Chiodetti.

From Sir Redvers Buller to the Secretary of State for War, dated March 30th, 1900:—

Medical officers attached to regiments and corps.—Major S. Butterworth, Major H. B Hinde, Major A. S. Rose (wounded), Captain M. L. Hughes (killed), Captain R. H. E Holt (killed), Captain N. Tyacke, Captain J. H. Campbell (wounded), Captain C. Dalton (dangerously wounded), and Lieutenant H. B. Onraët (killed).

Medical officers with bearer companies.—5th Brigade, Major S. Townsend; 10th Brigade, Captain C. Martin; 4th Brigade, Major E. O. Milward; 2nd Brigade, Major J. E. T. Reckett; 6th Brigade, Major T. B. Winter; 11th Brigade, Major Haywood; 5th Brigade, Captain E. M. Morphew; and 6th Brigade, Captain J. D. Alexander.

Medical officers with field hospitals.—2nd Field Hospital, Major J. T. Culling and Captain H. J. Parry; 4th Field Hospital, Major G. T. Goggin, Major F. S. Henston, and Lieutenant and Quartermaster R. Adams; 5th Field Hospital, Major G. H. Younge, Captain E. M. Pilcher, and Lieutenant and Quartermaster J. Hirst; 6th Field Hospital, Major J. B. W. Buchanan and Captain N. Faichnie; 10th Field Hospital, Major E. R. Cree; 11th Field Hospital, Major J. D. Moir, Captain F. G. Faichnie, and Major A. Fitzgerald; 2nd Division Field Hospital, Major A. Baird; and 5th Division Field Hospital, Major J. G. Black.

Volunteer Ambulance Corps.—Major H. Wright, Gordon Highlanders; Captain Lord R. Manners, King's Royal Rifle Corps; Lieutenant E. M. Baker, Manchester Regiment; Lieutenant C. W. McD. Findlay, Gordon Highlanders; Second Lieutenant J. R. E. Stansfield, Gordon Highlanders; and Second Lieutenant P. D. Stewart, Gordon Highlanders.

Indian Ambulance Corps.—Mr. Clarence, superintendent; Mr. Ghandi, assistant superintendent.

The medical arrangements have been everything that could be desired. I am sure that I only express the feelings of the whole force when I say everyone is grateful to Sir William Mac Cormac, Mr. Treves, and Sir William Stokes, whose skill has saved several lives and mitigated much suffering, and whose knowledge and experience have been a blessing to the sick and wounded.

Colonel T. J. Gallwey, C.B., principal medical officer, has devoted himself to his work with marked success, and it is largely due to his great administrative powers and forethought that everything has worked so smoothly.

Colonel J. A Clery, who has been in charge of the general hospital at Mooi, has displayed great powers of organisation and readiness to overcome difficulties. His hospital is a source of admiration to all who have visited it.

Lieutenant-Colonel W. B. Allin has been principal medical officer of the force in the field, and has had to make all the arrangements for the evacuation of hospitals and the removal of the wounded, which have, under great difficulties, been performed with great regularity, and yet with the greatest consideration for the wounded.

Lieutenant-Colonel P. H. Johnston has been most successful in his management of the general hospital at Pietermaritzburg.

Colonel Gallwey mentions in the highest terms the assistance he has received from his secretary, Major W. Babtie. I have already recommended this officer for the Victoria Cross in recognition of his gallantry at Colenso on Dec. 15th.

Lieutenant E. T. Inkson's name has been specially mentioned to me for having habitually distinguished himself in action and for his care of the wounded under fire.

Where all have worked so well it is difficult to discriminate, but the names of the following officers have been specially brought to my notice:—

Line of communications hospitals.—No. 4 Stationary Hospital, Major B. Kirkpatrick and Major R. Mallins; No. 1 Stationary Hospital, Major F. A. B. Daly; and Estcourt Hospital, Major W. S. Dowman.

General hospitals.—No. 4 General Hospital, Major T. R. Lucas and Major S. F. Treyer; General Hospital, Pietermaritzburg, Major A. Dodd and Major T. Browning.

Hospital trains.—Major Brazier-Creagh and Captain Leumann, Indian Medical Service.

Base Depôt Medical Stores.—Major R. J. MacCormack.

Hospital ships.—Lieutenant-Colonel F. Hodder (retired pay), Major T. P. Woodhouse, Civil Surgeon Brodie, and Civil Surgeon Hamilton.

The Volunteer Ambulance Corps, under Major H. Wright, Gordon Highlanders, have shown great devotion and gallantry, and the Indian Ambulance Corps, under Superintendent Clarence, have been most careful of the wounded—the conditions of their enlistment did not allow them to go under fire.

From Sir Charles Warren, dated, Hutlings Farm, Feb. 1st, 1900:

With regard to the medical staff, they are deserving of all praise, and I do not like to pick out of the principal medical officer's report any particular case when the reports show that all behaved so well.

From Sir Redvers Buller to the Secretary of State for War, dated Laings Nek, June 19th, 1900:—

Royal Army Medical Corps.—Major J. D. T. Recktit and Major E. R. Cree.

I have to add to these certain officers of my staff who assisted General Hildyard in every manner in their power:—

Lieutenant-Colonel W. B. Allin, Royal Army Medical Corps, principal medical officer field force, who was in charge of all the medical arrangements, which were carried out to my entire satisfaction.

Major J. D. Moir, Royal Army Medical Corps, in charge of 11th Brigade Field Hospital, did excellent work after the action at Allemann's Nek.

Captain C. B. Martin, Royal Army Medical Corps, Commanding 10th Bearer Company.

Colonel H. S. G. Miles, M.V.O., chief of the staff.

Lieutenant-Colonel O. Todd, Royal Army Medical Corps, senior medical officer, 5th Division of General Hildyard's staff.

From Sir Redvers Buller to Lord Roberts, Nov. 9th, 1900:—

Medical Department.

Colonel T. J. Gallwey, M.D., C.B., has been principal medical officer of the Natal Field Force throughout. I believe that he has succeeded in maintaining on the lines of communication and at the front a higher standard of comfort in general, stationary, and field hospitals, and a better service in bearer companies than has ever before been attained with a force in the field. His unbounded energy and his unrivalled powers of organisation have aided him in this work, but beyond this he has shown a devotion to his work, a grasp of the situation, and a capacity of forethought that justifies me in saying that I consider his services eminently deserving of the highest consideration that can be given to them.

Colonel J. A. Clery, M.B., principal medical officer of the lines of communication is an officer of sound judgment, common sense, and high administrative power. In his hands the hospital at Mooi river became remarkable as a model of what a hospital should be and since that he has done most valuable service in supervising the hospitals and medical work along the lines of communication in Natal. I trust his services may be rewarded.

Lieutenant Colonel P. H. Johnston, M.D., did admirable work at a time of great pressure at the commencement of the campaign, showing much foresight and good powers of organisation.

The following medical officers deserve mention for the excellent duties they performed in connexion with general and stationary hospitals; Lieutenant-Colonel J. G. MacNeece, No. 7 General Hospital; Lieutenant-Colonel H. Martin, M.B., No. 14 General Hospital; Major T. R. Lucas, M.B., secretary and registrar, No. 4 General Hospital; Major F. A. B. Daly, M.B., No. 1 Stationary Hospital; Major H. H. Johnston, M.D., Mooi River General Hospital; Major G. W. Brazier-Creagh, excellent service with ambulance train; Major S. Westcott; Major R. J. McCormack, M.D., Base Depôt, Medical Stores; Lieutenant and Quarter-Master G. H. Painton, No. 4 General Hospital; and Lieutenant and Quarter-Master F. W. Hall, Howick General Hospital.

With the lines of communication such a great length the number of warrant and non-commissioned officers of the Royal Army Medical Corps who have in different places performed work that was locally considered worthy of special mention is naturally very large, and the same remark applies to the Militia and Volunteer Medical Staff Corps and St. John's Ambulance Brigade, to the army nursing sisters, to the *personnel* of the Indian Medical Service (who were attached), to the men of the Imperial Irregular Corps and the Natal Volunteers, to the large number of civil surgeons engaged in England and locally, and to the colonial nurses engaged locally, and from colonies over sea. I am quite unable to make a selection of the names that have been forwarded to me, and have forwarded the list to the Director-General, Army Medical Service, begging him to obtain, later, your permission to publish such names as he may think desirable, but I wish to record here my thanks to all the members of those organisations.

In dealing with the medical service of the lines of communication, I should fail in my duty if I did not express the gratitude of the whole force to the following: H.R.H. Princess Christian of Schleswig-Holstein for the gift of a hospital train, which has been the greatest blessing to our sick and wounded; the Red Cross Society, under Sir J. Furley; the Durban Women's Patriotic League; the Army Hospital Aid, Pietermaritzburg; Mr. A. Mosely for his munificent donation of the Princess Christian Hospital, Pinetown; Mr. F. Stevens, who gave the use of his house and grounds for the Princess Christian Hospital; Mr. Coope, who gave his yacht *Sunrise* for the use of sick and wounded officers; and Sir Samuel Scott who similarly took sick and wounded officers on board the *Golden Eagle*. These cases stand out, but there were many other instances too numerous to mention in which private individuals generously contributed to alleviate the sufferings of the sick and wounded, and in the name of the Natal Field Force I express our most grateful thanks to all of them.

Lieutenant-Colonel S. H. Carter, M.B., Royal Army Medical Corps, principal medical officer, 4th Infantry Division, has discharged his duties to my entire satisfaction.

Lieutenant-Colonel R. L. Love, M.D., Royal Army Medical Corps, and Major O. R. A. Julian, Royal Army Medical Corps, deserve mention for the manner they respectively looked after the 8th Infantry Brigade Field Hospital and Brigade Bearer Company.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Staff Surgeons: R. Miller to the *Eagle*, temporary; G. Wilson to the *Arrogant*; H. F. Iliewicz to the *Cambrian*; H. W. A. Burke to the *Pembroke*; J. L. Barrington to the *Mars*; and R. H. J. Browne to the *Alacrity*, on promotion. Surgeons: C. R. Nicholson to the *Cambrian*; W. P. Dyer to the *Nile*; E. A. Shaw to the *Medea*; A. F. Fraser to the *Resolution*; H. B. Hall to Yarmouth Hospital; E. Grazebrook to Hong-Kong Hospital; and H. H. Gill to the *Impregnable*.

VOLUNTEER CORPS.

The undermentioned Supernumerary Officers are absorbed into the Establishment of their respective Volunteer Corps on the disbandment of the City of London Imperial Volunteers, with effect from Dec. 1st, 1900, viz.:—*Artillery:* 2nd Middlesex: Surgeon-Captain A. Thorne. *Rifle:* 16th Middlesex (London Irish): Surgeon-Captain E. W. St. V. Ryan. 20th Middlesex (Artists'): Surgeon-Captain R. R. Sleman. *Royal Engineers:* Submarine Miners: The Forth Division: Neish Park Watt to be Surgeon Lieutenant. *Rifle:* 4th Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant H. C. Groves resigns his commission. 1st (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain T. Philip to be Surgeon-Major.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major S. P. Smith, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers. Surgeon-Major D. E. Flinn to be Surgeon-Lieutenant-Colonel.

AN EXPERIENCE OF ANTI-TYPHOID INOCULATION.

The January number of the *Medical Chronicle* contains an article, 28 pages in length, entitled, "Six Months with a Military Hospital in South Africa," written by Mr. J. W. Smith of Manchester, lately in charge of the surgical division, No. 9 General Hospital, South African Field Force. In the beginning of February, 1900, the Manchester detachment of the Medical Staff Corps was enrolled in the Royal Army Medical Corps and transported to Aldershot, and Mr. Smith, having been gazetted to a temporary commission in the Royal Army Medical Corps, was detailed to the staff of No. 9 General Hospital and sailed for South Africa early in March. The staff of No. 9 General Hospital consisted of 20 medical officers, of whom 13 were civilian surgeons and seven belonged to the Royal Army Medical Corps, including one officer from the London Volunteer Medical Staff Corps and Mr. Smith himself. The following is his description of what must have been the principal medical event of the voyage:—

On the voyage out we all underwent the process of anti-typhoid inoculation. This is by no means a pleasant experience. Thirty of us were done one afternoon, the dose, which consists of a sterile culture of the typhoid bacillus, being injected under the skin of the flank. Within two hours we were all prostrate. The effects came on suddenly, so much so that several men fainted, whilst some vomited and the majority had a well-marked rigor. The effects are pretty severe for two days and then pass rapidly away. On the second day there is a plaque of effusion as large as the hand round the point of puncture, the skin very red with much subcutaneous effusion and œdema, and red lines of lymphatics running upwards towards the axilla and downwards to the inguinal glands, which are swollen and tender. At this stage walking is by no means a pleasure, and the erect posture quite out of the question. Some had slighter local disturbance, and in them the constitutional symptoms were usually more severe. Personally, I had a severe rigor lasting for over an hour and a high temperature all night. Next afternoon another slight rigor, the temperature rising to over 101°, and on the third afternoon only a slight rise of temperature. No one demanded a second inoculation, which is strongly recommended to secure immunity lasting for some time. It is impossible to speak of the success of this anti-typhoid inoculation until the statistics of the war have been published. Professor Wright has already published them with respect to the Ladysmith garrison. In Ladysmith there were in round numbers 10,000 not inoculated, and 1700 inoculated. Of the non-inoculated one in seven took enteric, of the inoculated one in 48; the proportion of deaths amongst those attacked was very nearly the same in the two groups. The general impression amongst the medical officers in our hospital was that a single inoculation probably did not confer an immunity lasting very long—the length of time differing in individuals; and also that there was a tendency in the cases of enteric in inoculated patients to abort at the end of 10 or 14 days. I should say, however, that a very considerable number of our detachment who had been inoculated suffered from enteric, of whom four at least died. Of the medical staff the only member of the junior staff who had not been inoculated died of enteric.

SOUTH AFRICAN NOTES.

Civil Surgeon Kellage was slightly wounded in the railway action near Vlakfontein on Feb. 6th.

A telegram from Krugersdorp, dated Feb. 2nd, states that at an outpost engagement at Modderfontein on Jan. 31st Dr. Walker, who was among the killed, had received three

bullet wounds, but was finally despatched by a Boer, who battered in his skull with a stone.

The following have been discharged from hospital to duty:—Captain F. Smith, R.A.M.C., Civil Surgeons H. C. Adams, W. J. Moir, Brincker, H. Brown, and P. Stewart (Jan. 27th). Major W. L. Gray, R.A.M.C., Major G. E. Hale, R.A.M.C., and Major R. G. Hanley, R.A.M.C. (Feb. 3rd).

Civil Surgeon John Ironside Bruce is reported dangerously ill at Newcastle from enteric fever on Feb. 7th.

DEATHS IN THE SERVICES.

Surgeon General Stephen Chapman Townsend, C.B., I.M.S., at Exeter on Feb. 9th, aged 75 years. The deceased entered the Indian Medical Service in 1852, and was engaged in the Burmah campaign of 1852–3 (medal). He was appointed principal medical officer of the Kuran field force in 1878 during the Afghan war, and was chief of the medical staff under General Roberts in the Cabul expedition of 1879. He was severely wounded in the advance through the Shutagardar Pass whilst talking to General Roberts. From 1868 to 1878 the deceased was civil sanitary commissioner in the Chitral Provinces, and was appointed surgeon-general of the Punjab in 1880. On his retirement he received the C.B.

REVACCINATION IN THE ROYAL NAVY.

News was received at Plymouth on Feb. 5th that H.M.S. *Blenheim* had arrived at Port Said from Gibraltar *en route* for China. On the voyage the whole of the ship's company and the majority of the officers had been revaccinated. This is in accordance with an Admiralty order for ships proceeding to the China station.

Inspector-General of Hospitals and Fleets Henry Charles Woods has been promoted to a Commandership of his order.

"Audi alteram partem."

"THE SURGERY OF PREGNANCY AND LABOUR COMPLICATED WITH TUMOURS."

To the Editors of THE LANCET.

SIRS,—In his lecture published in THE LANCET of Feb. 9th, p. 382, Mr. J. Bland-Sutton says: "Some accoucheurs recommend in cases where a cyst obstructs the transit of the child that it should be emptied through a vaginal puncture (Herman)." I take it that anyone reading this would think that I advised tapping as a routine proceeding rather than the better treatment advocated by Mr. Bland-Sutton. This is not an opinion that I hold or have expressed. I therefore asked Mr. Bland-Sutton to correct this misrepresentation. I have received from him the following reply:—

48, Queen Anne-street, Cavendish-square, W.,
Feb. 11th, 1901.

DEAR HERMAN,—Being so often misrepresented myself, I always endeavour to present other men's views carefully and justly. I gathered your views on this matter from the Trans. Obstet. Society, vol. xl., p. 8. I have re-read them and find that you do recommend the practice as stated in my lecture and I fail to find any misrepresentation. I added your name because as a known teacher of obstetrics at a London hospital it gave sanction to the method when adopted by a practitioner not skilled in operative surgery. You will, if you read carefully, find in the lecture that I particularly criticise palliative measures instead of placing the patient in skilled surroundings.

Yours sincerely,
J. BLAND-SUTTON.

PS.—If you make any public reference to this matter also kindly include this letter.—J. B.-S.

I find in the remarks to which Mr. Bland-Sutton refers no recommendation of tapping, unless it be inferred from a general expression of agreement with the paper under discussion. (In this paper tapping is discussed so fully and impartially that I think it would be unjust to the author to say that he recommends tapping.) On the contrary, I pointed out the dangers of tapping, I advised that in circumstances which did not permit ovariotomy the cyst should be incised and stitched to the vagina, and I said that this should not be done when ovariotomy could be performed.

I would ask those of your readers whom this small question may interest to read the remarks referred to by Mr. Bland-Sutton, and judge how far his representation of them is a fair one.

I am, Sirs, yours faithfully,
Feb. 14th, 1901. G. E. HERMAN.

"DIPHTHERITIC PARALYSIS."

To the Editors of THE LANCET.

SIRS,—The interesting case reported by Dr. Rice Oxley in THE LANCET of Feb. 2nd, p. 321, is a good instance of how an attack of diphtheria attended by very mild symptoms may be followed by paralysis. Such cases are not particularly rare and have given rise to the notion that the frequency of paralysis bears no relation to the severity of the initial attack of diphtheria. Thus Gowers states that paralysis "is equally likely to follow attacks that are severe as those that are trifling." This appears to have been the general opinion, especially before the antitoxin treatment was discovered, although authorities were not unanimous on the point. I cannot help thinking that to a large extent this belief was due to the fact that the severity of the attack of diphtheria was often estimated from the history given by the patient, the symptoms having been so slight that no medical man had been consulted. In other words, the feelings of the patient and not the extent of the anatomical lesion—the symptoms and not the signs—were taken as the criterion of severity. It is a commonplace observation that membrane extensive enough to cover a large part of the tonsils may exist with only the very slightest malaise. Indeed, in some cases the patient may be unaware that the throat is the seat of the mischief. He may consider himself to be only slightly out of sorts, though in reality his attack is of quite average severity. Such cases are frequently met with among the staff of a fever hospital, so that the only safe rule is never to omit an examination of the throat, whatever may be the symptoms for which the patient seeks advice. In the following table, taken from a paper in the Metropolitan Asylums Board's report for 1898, I have classified 829 consecutive cases of diphtheria uncomplicated by any other infectious disease. The classification depends entirely on the amount of the local lesions, no account being taken of merely subjective symptoms.

Nature of case.	Total cases.	Cases of paralysis.	Percentage of paralysis.	Cases of severe paralysis.	Deaths from paralysis.
Severe ...	223	64	28·6	19	5
Moderate ...	566	75	13·2	7	1
Mild	40	—	—	—	—

The first group comprises cases with extensive faucial membrane with swelling of the glands and rhinorrhœa. In the group of mild cases the faucial lesion was slight, the diagnosis depending chiefly on the history of exposure to infection, confirmed in every case by bacteriological methods. The intermediate group contained cases with a moderate amount of membrane, and many of them, if classified according to the symptoms complained of, would have been considered very mild. Of the "severe" group, 128 patients died before paralysis had had time to develop. Out of the 95 survivors 64, or 67·4 per cent., became paralysed.

From the above table the following conclusions may be drawn: (1) severe attacks of diphtheria are especially liable to be followed by paralysis, often of a severe character; (2) in less severe attacks paralysis is less frequent; and (3) in mild attacks paralysis is improbable. Of course, I do not mean to deny that even the mildest attack may be complicated by paralysis, merely asserting that such an event is relatively infrequent. Two sources of fallacy are obvious: (1) that all exudation may have cleared up before the case comes under treatment; and (2) that membrane, though present, may not be visible by the ordinary method of examination. Making every allowance for possible errors, it is justifiable to conclude that the severity of an attack has a very definite relation to the frequency and character of the subsequent paralysis. Besides the amount of membranous exudation indications of the severity of diphtheria are found in the urine, the blood, and the heart. Albuminuria, anæmia, and disturbance of the heart's action are most marked in the severe cases, and each one of these signs serves as a warning of the possible approach of paralysis. In hospital work we have long been accustomed to estimate on

these lines the likelihood of paralysis supervening, and very useful help in treatment is thus obtained. It should be mentioned that all the cases in the above table were treated with antitoxin. In pre-antitoxic years I believe the rule just stated still holds good, though the problem is complicated by the fact that no treatment was available for preventing a mild case from becoming severe; and severe cases usually died. At the same time the diagnosis was less accurate than at present, bacteriological methods not being used. As patients who survived a severe attack were not numerous, a few cases of paralysis occurring among them would represent a high percentage. Thus, in the table I have given less than half the total paralysis was associated with severe attacks of diphtheria, though in consequence of the comparatively small number of such cases the percentage of paralysis is decidedly high. In patients at the present time admitted to hospital, and in consequence of the mildness of the disease not treated with antitoxin, paralysis is, I believe, very unusual. After all, this is only what one would expect, since with surfaces of equal absorptive power the absorption of toxins would vary directly with the extent of the membrane.

I am, Sirs, yours faithfully,

F. J. WOOLLACOTT.

Eastern Hospital, Homerton, N.E., Feb. 3rd, 1901.

THE EXCISION OF HÆMORRHOIDS.

To the Editors of THE LANCET.

SIRS,—I was glad to read your criticism of a recent publication on "Diseases of the Anus and Rectum" in THE LANCET of Jan. 26th, p. 261, in which you very justly comment on the two authors who condemn the removal of hæmorrhoids by excision. These two authors state that their objections to the operation by excision are "that it leads to a severe loss of blood, is tardy in healing, and is liable to cause ultimate contraction of the lower part of the rectum." I very much appreciate your remarks when you reply that "all these objections are imaginary and none of these evils result when operations are carefully performed."

My experience of excision, which now covers a vast number of cases and extends during a period of 25 years, has completely convinced me that when the operation is performed as directed, and the common intelligent principles of general surgery are observed there is no excessive hæmorrhage, and I can absolutely deny that the slightest contraction of the lower bowel ever can or ever does take place. Unless some of the skin at the verge of the anus is sacrificed—which would be a distinct violation of the instructions given for excision—no stricture of the anus ever results. Contraction depends entirely upon the removal of skin, and the contraction bears almost an exact relation to the amount of skin removed. Cutting away the small tabs just outside the anus is one of the treacherous snares which is common to all operations for hæmorrhoids and ought only to be resorted to with the greatest caution and consideration. As to convalescence I am positive that it is not only quicker but far more perfect than that following any other operation for the removal of hæmorrhoids.

I cannot understand how the authors referred to can consider themselves entitled to express their opinions on the merits of excision when they so naïvely boast that they never employ any other method than that of the antiquated ligature. The patients I operate upon by excision invariably have an action of the bowels on the fifth day and after that event they are at liberty to return home on the day following, and more frequently than not they are quite equal to resume their ordinary avocation within a fortnight. The ligature as applied to hæmorrhoids is after all only a relic of the principles which domioated mediæval surgery and cannot compare in rapidity of cure with excision. I may go further and assert that I have never after excision met with a single one of those numerous complications which other authors allege follow the use of the ligature. As a matter of fact, it was the tedium of recovery after using the ligature which originally induced me to abandon that practice for excision. What surgeon at the present day ligatures an artery when he can employ torsion? Early in my surgical career I recognised the absurdity and inconsistency of devising special and exceptional methods for removing a simple pathological condition like hæmorrhoids instead of treating them by the ordinary and rational rules of general surgery.

I am, Sirs, yours faithfully,

Manchester, Feb. 5th, 1901. WALTER WHITEHEAD.

"GASTRIC HÆMORRHAGE AND ITS SURGICAL TREATMENT."

To the Editors of THE LANCET

SIRS,—I have read with interest Mr. Robson's address on the above subject published in THE LANCET of Feb. 9th, p. 375. I think that many will agree with me that by including stomach cases in which chronic hæmatemesis happened to be one of the symptoms before or at the time of operation he puts the surgery of gastric hæmorrhage in an unduly favourable light. "Chronic" hæmatemesis, by which we mean coffee-ground vomiting, is, after all, only one of the symptoms of a disease which may or may not require surgical relief. It seems to me that there should be a very clear distinction made between operations on stomach cases in which chronic hæmatemesis is one of the symptoms and operations undertaken to save a patient's life during an attack of gastric hæmorrhage—acute hæmatemesis—which threatens to be fatal. The question at present vexing the minds of the profession is, Given a profuse and oft-recurring hæmorrhage from the stomach which is threatening life, are we justified in operating or should we trust to medical treatment? In other words, are we to operate for hæmorrhage *per se*, apart from the pyloric obstruction and other stomach disabilities produced by ulceration?

The five cases quoted give us a wrong impression because they are not all cases operated on for gastric hæmorrhage. The first case is a pylorectomy. The chronic hæmatemesis is only an incident in the case, for the result would have been the same had it not been present. The operation was for pyloric obstruction and cannot, therefore, be reckoned as supporting the argument for the surgical treatment of gastric hæmorrhage. I may add, for I know the case well, that the symptoms of pyloric obstruction rapidly reappeared and the patient died within the year. The hæmatemesis, therefore was only an incident in the course of a fatal disease which killed by symptoms other than bleeding. The second case should certainly be excluded as the operation was not performed on the stomach. Moreover, Mr. Robson is mistaken when he says that the patient was "vomiting bright arterial blood." In his report of the case in the *British Medical Journal*, July 10th, 1897, it is only recorded that "the patient was *said* to have vomited blood immediately after the accident." Now, I personally admitted the patient into the hospital. His fellow-workman told me that he thought blood had been vomited. I therefore assumed a "wound of the stomach." At the operation there was no wound of the stomach and I was therefore interested to notice if any sign of gastric hæmorrhage appeared subsequently. None ever occurred, so that beyond the workman's statement there was no evidence whatever of gastric hæmorrhage. These two cases should therefore be excluded. In the remaining three an operation seems to have been done in order to prevent a fatal result from a recurring gastric hæmorrhage, and this is the point that I wish to emphasise—namely, that the presence of "coffee-ground" vomiting is only one of the symptoms of a disease for which surgical interference may be necessary; but what we want deciding is whether we are justified in opening the abdomen on account of the sudden occurrence or recurrence of a "gastric hæmorrhage" so profuse as to threaten life precisely on the same lines as we have been taught to expose a bleeding point in other parts of the body.

I am, Sirs, yours faithfully.

Bradford, Feb. 9th, 1901. J. BASIL HALL.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS.—Your leading article in THE LANCET of Feb. 9th, p. 410, on the topic of legislation as applied to the disease of alcoholism should induce many useful thoughts in the minds of those who do not view the question from an intemperate standpoint. The facts which Dr. Carter has adduced are such as will impress the profession that this question must be viewed as one of the first importance by those who love their country. Personally I have never "signed the pledge," but have the reputation of being "strong on temperance" according to a local publican. Pardon me also if I say that I am an active organiser of

more than one branch of athletics. Being thus, perhaps, absolved from some of the prejudice which often clings around any man who feels strongly on the alcohol question, I would like to point out that for a general practitioner it is unpopular to profess a marked adherence to temperance principles. The publican's influence swings against him at once; and that, as everyone knows, means a certain loss of practice by no means small, especially if neighbouring medical men adopt a *laissez faire* attitude on the alcohol question. The fact is, that general practitioners have more reason than the "front rank" men for being shy of speaking the plain truth about alcohol. You may say to your patient without fear of offence, "You are not taking precautions about your sanitary state: your drains smell abominably"; but you will often give great offence if you say, "You are indulging too freely in alcohol: you smell badly of your continual nipping."

It is admitted that the abuse of alcohol is one of the worst evils affecting the British nation. No body of men know that better than the medical profession. Further, if the proved facts are admitted—if, for instance, it is admitted both that the habitual use of alcohol is unnecessary to most people and harmful to many, and that none of the alcoholic drinks in common use have any nutritive value whatever, surely it is time that we general practitioners should raise our voices loudly and unanimously against this national danger just as we have openly and emphatically condemned those breaches of sanitary laws which have in times past nursed the diseases of small-pox, typhus fever, or typhoid fever. At present we are not decided enough: we are not unanimous enough on the alcohol question.

I am, Sirs, yours faithfully,

Feb. 11th, 1901. A COUNTRY PRACTITIONER.

MR. VICTOR HORSLEY'S REPORT.

To the Editors of THE LANCET

SIRS,—I have read Mr. Horsley's report to the Registered Practitioners of England and Wales with rather mingled feelings. No one can have a higher opinion than I of my friend's energy, devotion to his constituents, and desire to be accurate as to his facts. But here his facts are incorrect and his dicta in the highest degree misleading. It is as nearly as possible the opposite of the truth to say that the representatives of the friendly societies would never consent to the question of a wage-limit being discussed at the Conciliation Board. On the contrary, this was one of the questions which were expressly deferred for discussion until such a Board would be formed.

I am, Sirs, yours faithfully,

WILLIAM BRUCE,
Direct Representative for Scotland on the
Dingwall, N.B., Feb. 13th, 1901. General Medical Council.

LEGISLATION FOR THE PREVENTION OF VENEREAL DISEASE.

To the Editors of THE LANCET.

SIRS,—I should be most grateful if any of the readers of THE LANCET would supply me with information, or indicate sources of information, concerning the workings of legislation for the prevention of venereal disease both at home and abroad? Is it possible to ascertain what proportion of the troops destined for South Africa were rejected for venereal disease?

I am, Sirs, yours faithfully,

G. ARCHDALL REID.
Netherby, Victoria-road S., Southsea, Feb. 10th, 1901.

A SAD CASE.

To the Editors of THE LANCET.

SIRS,—As chaplain to the deaf and dumb at St. Saviour's Church, 419, Oxford-street, W., I have had applications for help in getting work from a gentleman whose difficulties do not really lie within the scope of our work, for the reason that the gentleman is able to hear with a tube, being only partly deaf, and is not dumb. I write to THE LANCET because X, as I will call him, passed the second examination in medicine at the Royal University of Ireland in 1884 and is now but 35 years of age. Just as he was ready for his final scarlet fever partly destroyed his hearing and ruined his career. Ever since that X has honourably maintained himself as a dispenser until lately, when through the laying on of a telephone he has had to give place to another with perfect hearing. The situation he now holds at the sum of 25*s.* weekly he must soon give up for good reasons; meanwhile he bravely holds on, rising at 4 A.M. daily to go to this work, which is a long way off. Here is an educated man of refinement, practically an abstainer, a non-smoker, one who is not a broken-down hack or shabby genteel man ruined by vice, but one who can to all outward appearances still hold his own in society and has a cheerful manner and decent coat on his back. Will someone take him on as dispenser or clerk?—in a large business there should surely be room for one who is quick and full of sense though somewhat deaf. The case is fully vouched for by the names hereunder written: the late Samuel R. Mason, B.A., M.D. Dub., ex-Master of Coombe Hospital; J. Torrens M.D., M Ch. R.U.I., &c., late Demonstrator in Anatomy, Royal College of Surgeons in Ireland, 32 Harcourt-street, Dublin; D. M. Greig, M.B. Lond. Monkridge, Crouch-end-hill, N. (who last employed X); G. S V. Wills, F.L.S., Westminster College of Chemistry—and by yours faithfully,

F. W. G. GILBY,
Chaplain to the Deaf.

419, Oxford-street, London, W., Feb. 11th, 1901.

"THE STATISTICS OF MORTALITY OF 1900."

To the Editors of THE LANCET.

SIRS,—Will you oblige by publishing next week the birth-rate, death-rate, zymotic death-rate, and infantile mortality figures for the 33 largest towns, the 67 next largest towns, and the rest of England and Wales for 1900?

I am, Sirs, yours faithfully,

Feb. 8th, 1901. M. O. H.

*** As we have received several inquiries from local medical officers of health for the following statistics of mortality in 1900 we have decided to publish them for the benefit of those specially interested.—ED. L.

Birth-rate—England and Wales—28·9 per 1000.

—	Death-rate. All causes.	Death-rate. Chief zymotic diseases.	Infant mortality (per 1000 births).
England and Wales	18·3	2·00	154
33 great towns	19·5	2·50	172
67 other large towns	18·1	2·25	166
England and Wales less 100 towns	17·5	1·57	138

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Strain on the Indian Medical Service.—The Murder of Captain Johnston, I.M.S.—Further Development of the Plague Epidemic in Bombay City and Western Bengal.—The Health of the British Army in India.

FOR some few years officers of the Indian Medical Service have had hard work and very little leave. The shorthandedness of the service is at the bottom of the trouble, but I understand that proposals are on foot for taking in a certain number of men on nomination. In 1895 there was the Chitral campaign, which caused all leave to be stopped for many months. In 1897 there was the frontier trouble, when not only was all leave stopped but those on leave were recalled. In 1899 it was practically only possible for the accumulated leave to be taken by the seniors. Last year many men, after from 12 to 15 years' service, went on leave for the first time and were recalled later in the year. The China war caused all leave to be again stopped and every officer was recalled several even on the point of retiring had to come out to India again. It is important to note the very large contingent sent to China—viz., 130 officers for 17,000 troops and 8000 followers. Of these, 122 belonged to the Indian Medical Service. On the other hand, there have been in Calcutta for the past few months 10 medical officers without any patients until recently to look after. The great

strain has taken commissioned officers from numerous large districts, no less than 50 having been taken from civil to military employment. It has been pertinently asked why civil surgeons were not sent to China to man the base hospitals as was done in South Africa, instead of crippling the medical service of India. These continued difficulties have, I understand, led the Government of India to advise the admission of "outside" surgeons for certain appointments.

The murder of Captain D. C. Johnston, I.M.S., was particularly revolting. The murderer, a Ghazi, lay in wait near the entrance to the bazaar at Loralai armed with a sword and dagger to kill the first European he saw. Captain Johnston was going his rounds as civil surgeon when the fanatic rushed out on him and stabbed him to death in a moment. Captain Johnston was senior medical officer at Loralai in the Quetta command. He was only 30 years of age. Several of these outrages have occurred, and it is almost invariably the custom not to be content with the punishment of the fanatics themselves, but to make the community to which they belong suffer also for the crime.

Plague shows a marked increase during the past week. For the whole of India there were 2839 deaths, compared with 2463 during the previous seven days and with 1279 during the corresponding week of last year. There were 575 deaths in the Bombay Presidency, 1863 in the Bengal Presidency, 37 in the Madras Presidency, 23 in the Punjab, and 341 in the Mysore province. In Calcutta there were 78 cases with 76 deaths, including 34 returned under the head of "suspicious." In Bombay city there were 293 deaths from plague—a considerable increase over the previous week. In western Bengal plague continues steadily to increase. There were 1014 deaths in Patna district, 181 in Monghyr, 357 in Saran, and 230 in the Gya district. A slight recrudescence is reported in the Punjab and in the Kolar gold-fields it continues to increase. Bombay city had a mortality of 1119, equal to a rate of 68·97 per 1000 per annum. Of this number 222 were returned as due to plague, being an increase of 68. There is no doubt that the fifth outbreak is now developing and the disease is fairly distributed over the city. The disease shows the same virulence and lately several dead bodies have been found in the public roads.

The retirement is notified of Lieutenant-Colonel G. M. J. Giles, who will be especially remembered in connexion with his investigation of kala azar in Assam, his scientific researches on the subject of the deep sea fauna of the Bay of Bengal, and more recently with his work on mosquitoes.

Cases of Malta fever continue to be proved in the north-western districts of India. Cases of cerebro-spinal meningitis have been occurring for some months past in the city of Calcutta. It is probable that many of the rapidly fatal cases diagnosed as due to cerebro-spinal meningitis were in reality due to plague. With the exception of those officers engaged on the plague staff very few medical men in Calcutta have had any experience of plague, and it is only the later cases of cerebro-spinal meningitis which can be said to have been proved as due to that disease. This view of the history of this outbreak is supported by the fact that some of the early cases were recognised by an officer of the plague staff as due to plague.

It is satisfactory to learn from the latest blue-book that the health of the European army in India has much improved since 1898. There has been a diminution of disease under almost every head. Venereal diseases still continue to cause the largest number of admissions to hospital. It is interesting to note that in Bengal heatstroke, phthisis, and dysentery were more common than in the other commands; that in the Punjab enteric fever had the greatest prevalence; and that in Madras hepatic derangements were the most noteworthy. The mounted arm of the service appears to have the most sickness and the infantry the least. There was only one death from cholera. This is a record. Also only one death occurred from small-pox. In view of the large amount of malaria at Dum Dum and Barrackpore it is a question whether these places should not cease to be kept for military stations. There was a great decrease in 1899 both in the number of cases of enteric fever and in the mortality. The admission ratio fell from 36·9 to 20·6, and the death ratio from 10·17 to 5·14. Perhaps this is explained by the much smaller influx of drafts from England and that there was no field service. There were 1392 admissions and 348 deaths from enteric fever alone making 213 men constantly sick and a loss of service of 77,818 days. The results of inoculation for enteric fever, have not been decisive, but the figures show that the percentage of enteric fever among the inoculated was 20·45 per cent. as compared with 22·22 per cent. among the uninoculated of the same corps and with 25·14 per cent. in the army as a whole. As in former years it is proved that the ages between 20 and 25 are the most vulnerable and also the first year of residence in India. Seven cases of plague with two deaths were reported. In the whole army of India 2142 men were invalided, being 31·64 per 1000 of strength as compared with 38·09 in the preceding year. This result seems chiefly due to the smaller number of men invalided for ague.

Jan. 17th.

Further Development of the Plague Epidemic.—Native Expressions of Sorrow at the Death of the Queen-Empress.

Again this week there is an increase in the plague mortality. For the whole of India 3277 deaths are recorded, as against 2839 during the previous seven days. The increase is chiefly in Bengal and Bombay city. For the Bengal Presidency there were 2181 deaths, of which Patna recorded 1236 and Saran 559. In Bombay city there were 370 deaths from plague, while the general mortality rose from 1192 to 1337. In the Madras Presidency there were 35 deaths and in the Punjab also 35. In Calcutta 73 deaths were recorded. The mortality in this city continues to be much higher than it was last year, although at present there is not apparently more plague, the exceptionally cold weather of the present season, together with an outbreak of small-pox, probably accounting for the greater part of this increase.

It is gratifying to hear that the expressions of regret and sorrow for the death of the Queen-Empress are universal. From the different communities of the natives have been sent messages of profound sorrow, and the greatest respect has been shown by all classes. One hears from time to time all sorts of talk about the decline of the British power; but under the mournful circumstances of the Queen's loss every section of the people gives utterance to its grief. One native paper expresses the general feeling admirably: "She had the tenderest regard for her Indian children and the people of India gave her a mother's affection. We mourn for her as we do for our dearest parent."

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Salicylic Acid in Fruit Wines: Prosecution by the Health Committee.

Messrs. R. Paterson and Son were summoned under the Food and Drugs Act at the instance of the Health Committee, for selling ginger wine to which was added salicylic acid in the proportion of 13 grains to the pint and raspberry wine which contained 19½ grains of the same drug to the pint. Professor R. W. Boyce, for the prosecution, stated that he had fed a kitten exclusively on milk containing salicylic acid in the proportion in which it was found in the wine, and the kitten lost weight and died. In cross-examination he admitted that the kitten did not take much of the milk, which it appears was curdled by the acid. Mr. F. T. Paul stated that in his experience salicylic acid in full doses was apt to be attended by serious symptoms. Dr. A. S. F. Grünbaum, assistant lecturer on physiological chemistry at University College, Liverpool, stated that salicylic acid increased the action of the kidneys and led to an increase of uric acid—"the substance which forms stone." Asked whether the mucous membrane of the stomach or of the eye was the more sensitive to irritation, he said that there was no mucous membrane of the eye. For the defence Dr. C. J. Macalister and Mr. T. H. Bickerton said that they had taken the wines freely and given them to their households and that no evil results had been observed. Dr. T. R. Bradshaw had taken five grains of salicylic acid daily for a considerable period without any unpleasant effects whatever. The wine was meant to be drunk largely diluted with water, and he was confident that the presence of salicylic acid in the proportions stated was no contra-indication to its use. Counsel for the defence explained that the wines in question, being made from fresh fruit and free from alcohol, could not be made with a smaller proportion of antiseptic, owing to the tendency of the juices to ferment.

The stipendiary dismissed the case. This is the second time these manufacturers have been prosecuted within the last few months; last October the case was also dismissed by Mr. Kinghorn, the deputy stipendiary magistrate

The Dangers of Overhead Electrical Wires.

During a snowstorm last week a bunch of telephone wires, becoming overweighted with snow, fell across the overhead electrical wires in connexion with the tramway system now so general throughout the city. The telephone wires, which immediately became charged with electricity, came in contact with a number of pedestrians, causing them severe electric shocks. Many people became entangled in the wires and writhed about in an agony of convulsions for a long time before they could be extricated. Unfortunately two men were found to be dead upon removal to the hospital, whilst 20 or more individuals were taken to the Royal Infirmary and were found to be suffering from severe injuries, such as burns and extensive lacerations of the integuments, besides injuries to the nervous system caused by shock. An inquiry into the circumstances attending the two deaths is being held by the city coroner. It is sincerely to be desired that the responsibility for the lamentable occurrences may be placed upon the proper shoulders. The introduction of the electric cars into Liverpool has already been attended by many disasters. The proximity of telephone wires to the trolley wires, which are charged with a high voltage, is a danger to life which should not be tolerated, and it is time for the public to demand that some degree of safety in the neighbourhood of the electric tramway lines be assured to them.

The Royal Infirmary; Annual Meeting; the Vacant Honorary Physiciancy

The annual meeting was held on Jan. 30th at the boardroom of the infirmary. The Lord Mayor and the Bishop of Liverpool were specially invited to attend. The bishop, in proposing a vote of thanks to the honorary physicians and surgeons, alluded to Dr. T. R. Glynn's long services to the hospital, which he eulogised in flattering terms His lordship said that, as one connected with the medical profession all his life, he thought he was justified in saying that the part of the work which a doctor liked best was his hospital work. Work which was thus well loved was sure to be well done, and not only was it well done but it was done at the cost of great self-sacrifice. His lordship concluded a sympathetic speech by proposing the appointment of Dr. Glynn as consulting physician, which was unanimously carried. The bishop also alluded to the generosity of Mr. George Melly, a member of the committee, who had provided the installation of the electric light in the wards and corridors at his own cost. It is expected that Dr. T. R. Bradshaw, the senior assistant physician, will have an unopposed election. It is generally recognised that Dr. Bradshaw has earned his promotion to the higher post of honorary physician.

The Royal Southern Hospital.

At the annual meeting of the subscribers to the Royal Southern Hospital on Feb. 11th, the treasurer's statement showed a very unsatisfactory state of things. The debit balance, which at the end of 1899 was £4140, had now increased to £7170. The president made an earnest appeal for funds to support the only general hospital at the south end of the city. During the course of the meeting Mr. Alfred L. Jones intimated that his firm (Elder, Dempster, and Co.) would increase their subscription to £50 a year and also give a donation of £500 towards the reduction of the debt. It also transpired that a further donation of £500 had been received from Mr. F. J. Harrison. Alderman Paull also promised to double his subscription and he appealed to others to do the same. There is now every prospect of a large reduction of the hospital debt, if not its total liquidation, by the assistance which, in due time, it will receive from the proportion of the Lord Mayor's hospital century fund, which is progressing satisfactorily, more than half the amount asked for by the Lord Mayor having been already subscribed. The annual dinner, which had been arranged for Feb. 12th, in conjunction with the Liverpool School of Tropical Medicine, and which the Duke of Northumberland, the Earl of Derby, Professor Ray Lankester, and others had promised to attend, will not take place owing to the national mourning and the death in Brazil of Dr. Walter Myers.

Another Disruption at the Cancer and Skin Hospital.

The income of this charity does not appear to be altogether satisfactory. The treasurer's report states that there is a credit balance of £196 16*s.* 1*d.* as against a debit balance of £217 on Dec. 31st, 1899. This apparently satisfactory result had, however, only been arrived at by the expenditure of capital. Legacies and donations, instead of being invested, have had to be used as current income. An undercurrent of feeling appears to exist in the management of the charity in spite of the lessons of former troubles. Colonel Pilkington, the chairman of the hospital committee (one of the new members elected since the resignation of the old committee, which has already been recorded in THE LANCET),[1] was opposed by a clique at the annual meeting held on Feb. 11th and was defeated by a small majority. Colonel Pilkington accepted a seat on the committee at a time when it was difficult to get anyone to serve. In the words of Mr. A. T. Miller, a member of the committee, "he had endeavoured to do his duty and had had to thwart the designs and ambitions of some people." Truly the charity is still in troubled waters. Will this latter evidence of discord encourage the Hospital Sunday and Saturday Committee to restore to the hospital the grant which under pressure of public opinion was withdrawn a year ago?

Feb. 12th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Plague in Cardiff.

THE suspicion that the man who died from plague at Cardiff on Jan. 31st was infected by a plague-stricken rat has been verified by Dr. W. G. Savage who has reported that in one rat which he examined plague bacilli were found to be present in large numbers. The corporation has announced by public advertisement that the sum of 4*d.* will be paid for every rat guaranteed to have been caught within the borough or port sanitary district and delivered at the corporation depôt. There are three official rat-catchers in the employment of the corporation and this number has been temporarily increased to six. The practical utility of the Cardiff and County Public Health Laboratory is emphasised by Dr. E. Walford in his report for the last quarter of 1900 when he states that in connexion with the October case of plague the facilities offered by the laboratory enabled a provisional diagnosis to be given 18 hours after the patient was seen by the bacteriologist. Upon a subsequent page of the same report we are told that the cook of a steamship was removed on Dec. 31st, 1900, to hospital presenting symptoms of plague with inguinal and axillary glands on both sides of the body slightly enlarged and inflamed. Some blood and exudation from the glands were taken for bacteriological examination, the results of which were completely negative, and the case was treated as one of septicæmia.

Insanitary Houses in Cardiff.

Although Cardiff is one of the oldest towns in the kingdom it did not increase in size to any very considerable extent until the latter half of last century. In 1881 the population was about 80,000 and it is now estimated at 200,000. One is not surprised, therefore, to find in a report of the medical officer of health presented to the Health Committee on Feb. 4th that there are in the town comparatively few slums or courts. The report, which is apparently made in compliance with sec. 32 of the Housing of the Working Classes Act, 1890, refers to 134 houses in different parts of the town containing an aggregate of 331 rooms and with a total population at the time of inspection of 395 persons. Dr. Walford represents that 129 of these houses in 28 groups are unfit for human habitation and the committee adopted his suggestion that they should be dealt with in accordance with the provisions of sec. 32 of the Act of 1890. The report does not state when the houses in question were erected—an omission which is to be regretted in view of the fact that until quite recently the building by-laws in force in the borough were not by any means based upon the most approved lines.

Remuneration of Colliery Surgeons.

It has been well known that the colliers in South Wales have been earning during the past year unusually good wages—10*s.* a day is said to be the average—and at the Merthyr County Court last week it was proved that several

[1] THE LANCET, August 5th (p. 366) and 19th (p. 515), 1899.

defaulting debtors were colliers earning considerably more than this sum. It is gratifying to know that those colliery surgeons who are paid by a poundage—usually 3*d* in the pound—upon the men's earnings have now an opportunity of recouping themselves for the losses which they sustained during the recent five months' strike, when many of them received no payment at all although there was no diminution in the attendance upon the colliers and their families.

Remuneration of Medical Officers of Health.

Judging from several recent instances the Local Government Board seem to have decided that the minimum salary of a medical officer of health who devotes his whole time to the service shall be £500 per annum. The Merthyr Urban District Council, the medical officer of health having recently resigned, propose to pay his successor a salary of £400 per annum, rising by annual increments of £25 to £500 per annum. The Local Government Board do not refuse their sanction to this salary, but will not agree to the requirement that the officer appointed shall devote his whole time to the duties, until the salary shall have reached £500. The appointment will be for a period of five years and will be made on March 6th next. There is no town in South Wales which requires more vigorous sanitary administration than Merthyr, and it is a great pity that the Local Government Board cannot get the district council to appreciate the full extent of their responsibilities.

Liabilities of Medical Officers of Friendly Societies.

A case of considerable importance to the surgeons of friendly societies was heard before Judge Owen at the Barry County Court on Feb. 5th. A member of the Barry lodge of the Ancient Order of Foresters who was suffering from pleurisy was attended on Nov. 20th, 1900, by Mr. P. J. O'Donnell, the surgeon to the lodge, who when he called at the man's house on the following day found the door locked and was unable to gain admittance. Later in the day and during surgery hours the patient's wife asked Mr. O'Donnell to visit her husband the same evening. He replied that as he had seen the man the previous day and had already called at the house once that day he could not see him again until the following morning. The woman thereupon called upon another medical man to attend her husband and his fees, amounting to 21*s.*, were sued for in the county court. A special meeting of the lodge had been held to inquire into the circumstances of the case, and Mr. O'Donnell had been exonerated by the members from all blame in the matter. The county court judge, however, held that he should have attended when asked to do so by the patient's wife, and gave judgment in the man's favour.

Small-pox at Barry.

Upon the arrival at Barry of a Spanish steamer from Barrow-in-Furness, on Feb. 6th, it was found that three members of the crew were suffering from small pox. They had been vaccinated, together with the remainder of the crew, at Barrow a few days before owing to the occurrence of a fatal case of small-pox among the sailors on board. A fourth case was found on Feb. 9th on a steamship which had left Cardiff on the day before. The Barry Urban District Council have had plans prepared and have even received tenders for a small-pox hospital, but in consequence of the opposition of some of the townspeople the erection of the buildings has been indefinitely postponed. Fortunately, however, the town possesses a very well-appointed hospital for the isolation of infectious diseases other than small-pox and the medical officer of health (Mr. George Neale) has very properly refused to allow it to be occupied in view of a contingency such as the present arising. His forethought is now fully justified, for the four men in question were promptly removed to this institution. It is to be hoped that the opponents of the council will now withdraw their opposition, which they must see is most ill-advised and not at all conducive to the best interests of the town.

Newport Medical Society.

An ordinary meeting of the members of this society was held on Jan. 30th, Mr. Walter Basset, the president, being in the chair.—The honorary secretary (Dr. J. Howard-Jones) was instructed to enter upon the minutes of the meeting the profound regret of the society at the death of the Queen.—Mr. A. Falconer Hayden exhibited a case of Sarcoma of the Humerus of large size and very rapid growth in a girl of 17 years, and Dr. A. Garrod Thomas brought before the members a case of Infantile Paralysis affecting Muscles around the Shoulder Joint. Curiously enough both patients had in the first instance been treated by bone-setters for injuries.—Mr. J. Lynn Thomas and Dr. A. William Sheen, two members of the society who have recently returned from South Africa, gave some details of their experiences, Mr. Thomas with the Welsh Hospital and Dr. Sheen with the Langman Field Hospital Limelight views taken by both the speakers were thrown upon the screen, and they included two photographs of the Dutch commander De Wet which had been taken by Dr. Sheen. From the remarks that were made it was evident that the Welsh Hospital and the Yeomanry Field Hospitals were thoroughly efficient.

South Devon and East Cornwall Hospital.

The annual meeting of the subscribers of this institution was held at Plymouth on Feb. 8th. The medical report stated that during 1900 the in-patients numbered 1282, an increase of 38 compared with 1899. There were also 2654 out-patients treated against 2650 in the previous year. 287 patients had been sent to the Pearn Convalescent Home, against 253 in 1899. The financial statement showed that the income amounted to £6492 and the expenditure to £6755. During the past year a donation of £2000 had been received from Mrs. F. Cubitt, and in December last the trustees of the late Mrs. E. S. Hains sent £21,000 to form a fund to be called the "Elizabeth Hay Fund."

Clifton Dispensary.

The eighty-eighth meeting of the subscribers of the Clifton Dispensary was held on Feb. 5th under the presidency of the Rev. G. Hemming. The medical report stated that 3451 patients had been treated during 1900, including 73 cases of midwifery, as compared with 4203 in 1899. The financial statement showed that there was a favourable balance of £127. 20 patients had been sent to the Jubilee Convalescent Home at Clifton.

Feb. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on Feb. 5th, Dr. Fraser, the President, being in the chair. At the commencement of the proceedings it was unanimously resolved that the College present to His Majesty King Edward VII. an address of condolence on the death of Her Majesty Queen Victoria and of congratulation on His Majesty's accession to the throne.

Dr R. M. Ronaldson was introduced and took his seat as a Fellow of the College. Mr. Tom Henry Trevethan Frampton was admitted by ballot to the Fellowship of the College. On a ballot the following candidates were admitted to the Membership of the College after examination: Dr. Noel Dean Bardswell, Banchory; Mr. Charles Plumley Childe, Southsea; Dr. George William Hamilton Cumming, Torquay; and Dr. Charles Harold Johnson, Edinburgh. The Registrar reported that since the last quarterly meeting 33 persons had obtained the licence of the College by examination.

The Curator submitted his report for the past year regarding the research and reporting undertaken in the laboratory during the year and the expenditure incurred. The report showed that 25 workers had been engaged in research, 1122 specimens had been reported on, and the expenditure had amounted to £822 6*s.* 10*d.* The arrangements which had been concluded between the College and the town council, by which the bacteriological diagnosis of suspected cases of tubercle, diphtheria, and enteric fever occurring among the citizens of Edinburgh is carried out in the laboratory at the expense of the town, had been in working order for some months. Negotiations were in progress between the College and the Local Government Board, whereby it was intended that the bacteriological examination of suspected cases of plague would be conducted within the laboratory on payment of a fee for each report identical with that paid by the English Local Government Board. A special department of the laboratory, isolated from the rest of the premises and judged suitable by the President (Dr. Fraser), had been set apart for the purpose.

Dr. Alexander Bruce was after examination recognised as a lecturer in Practice of Medicine and Dr. William Wood

was similarly recognised as a lecturer on Materia Medica and Therapeutics, the President conferring on them certificates of qualification.

The Parkin Prize, which is in the gift of the College, was awarded after competition equally between Dr. W. G. Aitchison Robertson and Dr. Noel Dean Bardswell. The subject of the essay on the present occasion was in terms of the deed of bequest: "On the effects of volcanic action in the production of epidemic diseases in the animal and in the vegetable creation and in the production of hurricanes and abnormal atmospherical vicissitudes."

A letter was submitted from the Principal and Vice-Chancellor of the University of Glasgow inviting the College to take part in the celebration of the ninth jubilee of the University. It was unanimously agreed to accept the invitation and remitted to the council to prepare an address of congratulation for presentation on the occasion.

Aberdeen Royal Infirmary.

The annual report shows that the total income for the year 1900 was £11,708 9*s*. 4*d*. and the expenditure £12,032 1*s*. 11*d*., leaving a deficit in the year's work of £323 12*s*. 7*d*. The number of occupied beds has increased from 202·3 to 207·5, and along with other institutions the hospital has suffered from the high prices prevailing for coals, provisions, &c. The cost per occupied bed thus rose to £50 13*s*. 9*d*., compared with £48 0*s*. 7*d* in 1899. The donation of £25,000 by Lord Mount-Stephen enabled the whole debt on the institution to be cleared off, leaving a balance to the good of £11 6*s*. 5*d*. On buildings in connexion with the jubilee extension scheme there has been a total expenditure of £75,297 7*s*. 8*d*. The revenue for the year included £68 10*s*. for medical students' fees. At the Convalescent Hospital, Cults, 252 patients were received and treated during the year. The total expenditure was £612 5*s*. 2*d*., being £24 0*s*. 7*d*. above the income for the year.

Aberdeen Royal Asylum.

The number of patients in the Royal Lunatic Asylum on Dec. 31st last was 887. During last year there were 308 admissions, 81 discharges, and 81 deaths. The building improvements have gone on steadily, and the new hospital wings have relieved the overcrowding of patients in the main asylum. Additional ground has been purchased in Aberdeen, and the branch at Daviot has been restored and the furniture which had been destroyed by fire there has been replaced. The total income for 1900 was £32,618 5*s*. 1*d*. and the expenditure was £29,317 7*s*. 3*d*., leaving a surplus of £3300 17*s*. 10*d*. The report by Dr. W. Reid, the medical superintendent, shows that though there were many difficult and anxious cases to treat there were no serious accidents during the year.

Small-pox in Glasgow.

The number of patients officially reported under treatment on Feb. 11th was 436, a number only eight in excess of the total a week earlier. Considering the rapid rate of advance which marked the course of the epidemic in its earlier phases the record just quoted is relatively satisfactory. But it must be remembered that many of the patients admitted to hospital during January are now convalescent and are being discharged. Thus a mere comparison of the weekly totals gives too favourable a few of the facts of the epidemic. On the whole, however, the position and outlook are improving. The new cases, as the figures just quoted show, are only occurring in sufficient numbers to keep the total number under treatment substantially the same as it was a week ago. With few exceptions, too, the admissions come from the recognised infected areas. Revaccination has become much more popular, and it is only just to the public to add that there has been little or no disposition to indulge in panic or to listen to exaggerated or alarming statements. So far the sanitary authorities have found no time to issue a tabulated statement of the details of the epidemic. Their energies, as can readily be imagined, have been severely taxed, and it is to be hoped that soon they will be able to claim that the epidemic is stayed.

Scottish Triple Qualification.

The last quarterly conjoint examinations of the Scottish Medical Corporations were distinguished by a very high percentage of rejections, the significance of which may possibly be open to various interpretations. The facts are as follows. At the first examination of 26 candidates nine passed; for the second examination, 35 candidates entered and 13 passed; at the third examination, 22 passed out of 30 candidates; and of 74 entrants for the final examination, 35 were successful. The high percentage of rejections in the earlier examinations is noteworthy.

Return of a Medical Officer.

Dr. Hugh Colligan Donald has recently received a cordial welcome from his numerous friends in Paisley on his return from South Africa, where he has been serving for over a year. Shortly before he sailed for home Dr. Donald had the misfortune to sustain a fracture of the leg, from the effects of which, however, he has now practically recovered.

Professor Cleland on Education.

At a recent meeting of the Educational Hand-work Association of Scotland an address was delivered by Professor Cleland, F.R.S., who discussed the value of the promotion of manual dexterity as a means of cultivating the intelligence. Professor Cleland, after alluding to the fact that the early mental processes of the child were all concerned with sense impressions or muscular efforts, considered it was rational that in the training of children use should continue to be made of the method by which nature had already taught them so much. It was necessary, however, that exercises should be chosen which would teach the child to observe and to think, actions capable of being performed by routine having necessarily but little mental educational value. Modelling and drawing were commended as specially valuable methods of training for children.

Feb. 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Direct Representative for Ireland.

SIR WILLIAM THOMSON has been re-elected Direct Representative for Ireland upon the General Medical Council. He received 1130 votes, against 245 given for Mr. T. Laffan of Cashel.

Belfast Medical Students' Association.

THE fourth annual meeting of this society was held in the students' union of Queen's College, Belfast, on Feb. 5th, the President (Mr. Walter Phillips, B.A.) being in the chair. The President introduced Mr. J. E. MacIlwaine, B.Sc., who gave an account of his experiences as dresser with the Irish Hospital which was sent by Lord Iveagh to South Africa. The paper, which was admirably illustrated by a series of slides prepared from photographs which had been taken in Africa, gave an extremely interesting account of the good work which had been done by the Irish Hospital, and, coming from one who took such a personal part as the author did in all details of the work, it presented a very vivid picture. The staff of the Irish Hospital saw little surgery but an immense deal of medical ailments, especially enteric fever, which apparently is almost invariably returned as "simple continued fever" Many of the cases of this disease treated were very severe, and Mr. MacIlwaine spoke hopefully of the results of inoculation against the disease but thought that the immunity gained was not a very long one. Several of the college medical professors and of the Royal Victoria Hospital staff who were present spoke in very commendatory terms of Mr. MacIlwaine's most excellent paper.

North of Ireland Branch of the British Medical Association.

The adjourned winter meeting (owing to the death of the late Queen) was held in the Belfast Museum on Feb. 7th, Professor John W. Byers, the President, being in the chair. Dr. T. S. Kirk showed a girl in whom he had by operation restored the nose after Lupus. Dr. J. B. Moore showed the specimens from a case of Gastro-jejunostomy. Professor T. Sinclair showed a series of Vesical Calculi of unusual size removed by suprapubic cystotomy, and a number of Gall-stones removed from a case of persistent jaundice in a woman. Dr. Moore read notes of a case of Perforated Gastric Ulcer successfully operated on; Dr. A. B. Mitchell read notes of a case of Hour-glass Stomach (the result of cicatrisation following an ulcer) which had been successfully operated on; and Dr. W. Calwell read a paper on When Should a Case of Chronic Dyspepsia be Explored by the Surgeon? These communications led to a most interesting discussion on recent advances in the surgery of the stomach in which the following took part: Dr. P. Redfern, Dr. A. Fullerton,

Dr. A. Dempsey, Professor Sinclair, Dr. J. S. Darling (Lurgan), and the President. It was brought out in the debate that the first successful operations in Ireland for a perforated gastric ulcer and for hour-glass contraction of the stomach were done by two Belfast surgeons, and that up to the present date 21 cases of operation for perforated gastric ulcer have been done by Belfast surgeons, with 12 recoveries, within the last three years.

Portaferry Dispensary District.

Mr. E. Smyth was on Feb. 9th elected by the Downpatrick Board of Guardians as medical officer of the Portaferry Dispensary District.

The Belfast Lunatic Asylum.

The visiting committee reported to the committee of management of the asylum on Feb. 11th that they endorsed the statements made by Sir G. P. O'Farrell, the Government inspector, in regard to the great insufficiency of accommodation, particularly for female patients, there being an excess of 228 inmates beyond the certified limits of accommodation in the establishment. It would appear that out of 322 admissions during last year 188 were received from the workhouse, as compared with 72 in the previous year. In reply to inquiries as to the cost of construction of asylums of various types the medical superintendent, Dr. W. Graham, said that at Aberdeen the cost of the villa type was £142 per bed, at Berlin £200 per bed, at Leipsic £142 per bed, at Birmingham £415 per bed on the pavilion or corridor plan (and this did not include the land); at Canterbury it was £460 per bed, at Croydon £458 per bed, and in East Sussex £282 per bed, but none of these sums included maintenance. He had no doubt that it would be cheaper to erect on the villa colony system rather than to build one huge establishment. The proposed asylum for Belfast was for 820 patients, and with land, furnishing, and equipment it would run to almost £300 per bed. They used their land up very largely in this system. A resolution approving of the adoption of the villa system as recommended by the medical superintendent was carried; and it was agreed that the surveying of the ground should be carried out by the borough surveyor's department, and that a ground plan should be prepared with the advice and coöperation of the medical superintendent as to where the villas should be placed.

Feb. 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Alleged Scandal with regard to a Post-mortem Examination.

A FORTNIGHT ago the daily press discovered an alleged scandal which gave the opportunity of writing many articles against the medical profession. Last year a police official named D—— met with a carriage accident. He was laid up for some months and was finally admitted to a hospital where he died some days after admission. His widow, on the advice of her friends, tried to exploit the accident with a view to getting damages out of the owner of the carriage which was the cause of the accident. The hospital authorities certified that the patient had died from alcoholic cirrhosis. The presiding judge ordered an inquiry and Dr. Socquet was bidden to make a post-mortem examination on the body which had been buried for nearly a year. According to the daily press Dr. Socquet was much surprised to find that the body had been disgracefully treated. The skull had been opened and in place of the brain it was found to contain some old newspapers and some tow. The viscera were missing from the abdomen and the thorax, which cavities contained three livers and sundry foreign bodies, such as cigarette ends, pipe-stems, string, vegetable peelings, and the various rubbish generally found in a room, which had apparently been emptied into the body. Of course there was a great scandal and interviews were published with the Director of the St. Antoine Hospital, with Dr. Gilles de la Tourette, in whose wards the man died, with the Assistance Publique, with the *internes*, and generally with everybody except Dr. Socquet. Well, I learn from him that the whole story is an absolute invention, except that he found that a necropsy had been held on the body of D——. He knew that already, for the post-mortem examination had been held by permission of the family of D——; the foreign bodies, however, existed only in the imagination of the reporters. Nevertheless, to give some satisfaction, the Director of the Assistance Publique has revived an ancient regulation which has been vigorously put into action as regards the hospitals. The result will be the disappearance of pathological anatomy. As it is no post-mortem examination can be made without the express permission of the family of the deceased, a permission which is more and more rarely given But in addition, by the strict letter of the law now applied the operating pathologist cannot take away an organ, even in a granted post-mortem examination, without a special permit for each case which has to be obtained from the Director of the Assistance Publique. As a matter of fact, necropsies cannot be made within 24 hours of death and burial usually takes place as soon as possible after the examination, so that the medical man has only about two or three hours in which to make his examination. It will therefore be impossible for him, if he should come across any interesting pathological condition of an organ, to get the requisite permission from the director in the time at his disposal. As a rule this regulation is never insisted upon, so that its enforcement can only be considered as a pandering to the daily press. The last meeting of the Society of Legal Medicine gave the sequel to the matter. Dr. Gilles de la Tourette explained that the post-mortem room at his hospital was very small and held only two tables. If there happened to be many post-mortem examinations to make in one morning it was difficult to keep the various organs removed separate, and mistakes easily occurred when the post-mortem room porter was putting them back. The responsibility rested first with the porter, next with the authorities for not providing a post-mortem room of sufficient size for a big hospital, and, finally, with the examining magistrate, who should have been cognisant of the fact that a post-mortem examination had been already performed. Finally, Dr. Gilles de la Tourette asked his colleagues to appoint a committee which should demand both from the courts and the Administration the favour that post-mortem examinations and their results should be absolutely privileged (*secret absolu de l'autopsie*). M. Brouardel, who was prevented from being present, asked that a second meeting should be held, as he had some important information bearing on the case of D—— to bring forward. The matter was referred to a committee consisting of M. Piquet, M. Vibert, M. Lefuel, M. Constant, Dr. Gilles de la Tourette, and two other medical men versed in forensic medicine.

Hygiene in the Post Office.

The Minister of Commerce, Posts, and Telegraphs recently set on foot an inquiry into the hygienic conditions of post-office employés with special regard to the question of tuberculosis. He instructed one of the departmental medical officers, Dr. Mignot, to report to him on the matter. The report shows that tuberculosis is responsible for 36 per cent. of the deaths among the staff, a much higher rate than the general tuberculosis death-rate for the whole of France. As probably the death-rate among the office staff is higher than the rate among the out-door staff the Minister has adopted the conclusions of the report and has issued three regulations relative to (1) the improving from a hygienic point of view of post-office buildings; (2) a medical examination of applicants for employ in the department; and (3) the creation of a committee to investigate the best means of establishing a sanatorium for the use of post-office employés suffering from tuberculosis. None of the staff is allowed to spit on the floor, special spittoons being served out, and all floors are to be rubbed over with a damp cloth instead of being swept dry. It is much to be hoped that all the great State departments will follow the example set by the Minister of Commerce.

The International Psychological Institute.

Last week the International Psychological Institute was founded at Paris, being the outcome of a private society which was started with that end in view. The institute is directed by an international committee of organisation of which the chief members are as follows:—Germany: Freiherr von Schrenck; England;[1] America: William James; France: d'Arsonval, Bouchard, Duclaux, Marey, Sully-Prudhomme, and Th. Ribot; Italy: Lombroso; Russia: Mendeleieff and Ochorowicz; and Switzerland: Th. Flournoy. The society is composed of members of three classes (1)

[1] The English member of committee was the late Mr. Frederic Myers.

foundation members who subscribe 10,000 francs; (2) subscribing members (*donateurs*) who give a donation of 1000 francs or an annual subscription of 100 francs; (3) ordinary members who give a donation of 250 francs or an annual subscription of 20 francs. The address of the institute is 28, Rue Serpente, Hôtel des Sociétés Savantes. The work of the institute will comprise experimental psychology, the anatomy, physiology, and pathology of the nervous system, hypnotism and other psychical phenomena, and social and criminal psychology. It is intended that the institute should be an experimental centre where *savants* throughout the world may find laboratories and clinical material with which they may pursue their researches under conditions of scientific accuracy. The first lecture, which was given by M. Duclaux, was a great success and bodes well for the future of the new undertaking. A notable audience assembled in the lecture-room in the Rue Danton, where many ladies, members of the institute, members of the Academy, and members of the Academy of Medicine were present. The forthcoming lectures should be as good—those of M. Dussaud, Mr. Frank Hales (Cambridge), M. Bergson, M. Van Gehuchten (Louvain), and of M. Pierre Janet have been already announced. M. d'Arsonval, M. Tardes, M. Ochorowicz and M. Bairac will announce theirs shortly.

Feb. 13th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Public Health Service in Prussia.

THE public health service in the kingdom of Prussia, which in the opinion not only of the medical profession but also of the general public is no longer in accordance with modern requirements, will now be reformed. The present state of this service and the reforms proposed by the Royal Commission have been described in former numbers of THE LANCET.[1] Unfortunately, the thorough reform so much desired by public opinion did not meet with the approval of the Prussian Parliament for political reasons which it would take too long to explain to foreigners. It will be remembered that the Royal Commission proposed the formation of a board of health in every district and circuit and the providing of a laboratory for hygienic work in every province. The medical officers to circuits (*Kreise*), who had hitherto been receiving small salaries and were thus compelled to engage in private practice, ought, in the Commission's opinion, to be made fully-salaried Government officials and to be debarred from private practice. In Parliament, however, the majority of these proposals were not accepted, and there is no longer any question either of laboratories or of boards of health for districts or of the general appointment of fully-salaried medical officers. The "reform," in fact, is limited to the institution of local boards of health, where they are desired by the local authorities, whilst the appointment of medical officers with adequate salaries and no private practice will only take place in those districts where there is a great amount of work. Except in a very few of the larger towns the medical officers will continue to act as medico-legal experts. The hopes once entertained as to the goodwill of the Government in this matter have been small enough since the Bill became law, and they have been additionally disappointed by the new Budget for the financial year beginning on April 1st. The Government asks for funds for the appointment of only 21 fully-salaried medical officers out of 499 at present employed. The salaries when private practice is not allowed are very small, beginning with 3600 marks (£180) and rising to 5700 marks (£285). Moreover, they receive a sum for house rent and are entitled to pensions when they retire, and in the event of their death pensions will be granted to their widows and children. The second class, the medical officers with permission to practice, will form the great majority. Hitherto they have been receiving the ridiculous sum of 900 marks (£45), but now they will have from 2250 marks (£112 10*s.*) to 4200 marks (210), but no pension. Special medical officers to law courts are to be appointed in 15 cases only. The *Deutsche Medicinische Wochenschrift*, in criticising the Government proposals, states that the expenses of the "reformed" public health service are only 500,000 marks (£25,000) higher than they were before the reform. Dr. Wallichs, the district officer of health at Altona, forcibly remarks in the *Aerztliche Vereinsblatt* that care for the public health in Prussia continues to be a matter of secondary interest. He says that owing to the inadequate salaries paid to the medical officers who are debarred from private practice the great majority will prefer not to belong to this category but will rather remain in the second class with a still lower salary where they will have at least an opportunity of earning a livelihood by private practice. No reform at all would have been better than this "torso," which will for many years to come continue to be the organisation of the public health service in Prussia. Undoubtedly in this matter, so important for the public welfare, the leading State of Germany has been outdone by a good many of the smaller States where the sanitary organisation has been brought up to date.

[1] THE LANCET, Sept. 26th, 1896, p. 915, and April 24th, 1897, p. 1179.

Plague-infected Rats on Board Ship.

Some anxiety was felt lately at Hamburg when the port sanitary authorities found many dead rats on board the steamer *Pergamon*, and bacteriological examination showed that the animals had suffered from plague. The steamer and the cargo were therefore thoroughly disinfected and everything that the rats had gnawed was burnt by the fire brigade. No case of plague has subsequently occurred among the crew and the steamer has been allowed to leave for Italy.

The Imperial Council of Hygiene.

The regulations for the new Reichsgesundheitsrath (Imperial Council of Hygiene) have been published by the Federal Council. The council has been instituted in conformity with the new laws relative to epidemic diseases to be a consulting body in connexion with the Imperial Health Office. The members are elected by the Federal Council and the president and vice-president are appointed by the Imperial Chancellor. The membership is an honorary office and is tenable for only five years, after which time fresh elections will take place. The Imperial authorities and also the authorities of the individual confederated States have the right to send representatives to the meetings. The council is authorised to send commissioners to make inquiries in any part of the empire where intervention in hygienic matters seems to be necessary. There will be nine special committees of the council, the functions of which will be to take cognisance of the following subjects: (1) public health, including hygiene of dwellings, ventilation, &c.; (2) hygiene of food; (3) water-supply; (4) hygiene of factories; (5) epidemic diseases; (6) hygiene of hospitals; (7) the pharmacopœia; (8) hygiene of shipping; and (9) veterinary hygiene. The "plenum" of the council will meet only when convoked by the Imperial Secretary of State for the Interior. The proceedings are not public. It remains to be seen whether this programme will be realised and how often the Imperial Government will think it requisite to convoke the council. Care must be taken to prevent the council from coming into collision with the medical departments of the individual States which are very anxious to maintain their prerogatives in this respect, and whose influence is the greater as the executive is entirely under their control, whilst the Imperial Council of Health is only a consulting body without executive functions. Of the members of the council the following prominent names may be mentioned: Professor von Bergmann, honorary F.R.C.S. Eng., the well-known professor of surgery in Berlin University; Professor Binz of Bonn; Professor Buchner of Munich; Professor Flügge of Breslau; Professor Fränkel of Halle; Professor Gaffky of Giessen; Professor Gerhardt of Berlin; Professor Robert Koch, the bacteriologist; Professor Löffler of Greifswald; Professor van Noorden of Frankfurt; Professor Rubner of Berlin; Professor von Ziemssen of Munich; and many others.

Statistics of German Universities.

The number of students registered at the German Universities this winter is 34,363, as compared with 27,784 in the winter of 1894-95, so that an increase of 20 per cent. has taken place during the past six years. The attendance of students at the various universities is as follows:—6673 in Berlin, 4184 in Munich, 3584 in Leipsic, 1917 in Bonn, 1731 in Halle, 1638 in Breslau, 1350 in Tübingen, 1317 in Göttingen, 1230 in Heidelberg, 1218 in Freiburg, 1264 in Würzburg, 1132 in Strassburg. 1053 in Marburg, 967 in Erlangen, 874 in Königsberg, 847 in Giessen, 780 in Kiel,

733 in Munster, 726 in Greifswald, 681 in Jena, and 512 in Rostock. As regards attendance in the various faculties there are 2327 students of Protestant theology, 1584 of Roman Catholic theology, 10,511 of law and national economy, 7113 of medicine, 5200 of philosophy and history, 4722 of mathematics and natural science, 1157 of pharmacy, 1512 of agriculture, and 448 of dental surgery. Moreover, at the University of Giessen there are 126 students of veterinary medicine, but in other parts of Germany veterinary medicine is taught at special colleges not belonging to the universities. These figures, compared with those of the previous year, show that the students of Protestant theology have decreased by 86 and the students of medicine by 430. The students of other branches have increased considerably, especially the students of law, where the increase has been 47 per cent. during the past 10 years. At the University of Berlin there are 366 students registered in the faculty of theology, 2359 in the faculty of jurisprudence, 1312 in the faculty of medicine, and 2636 in the faculty of philosophy. With respect to nationality, 4679 students come from Prussia, 994 from the other States of the empire, and 714 from foreign countries. Of foreigners of European origin the majority (318) come from Russia, 112 from Austria, 88 from Switzerland, 62 from Hungary, 32 from Great Britain and Ireland, 22 from Italy, 20 from France, 20 from Roumania, 17 from Turkey, 17 from Servia, 16 from Bulgaria, 15 from Sweden, 15 from Greece, 12 from the Netherlands, 11 from Luxemburg, five from Belgium, four from Spain, three from Denmark, and one from Portugal. Of foreign students from distant parts of the world 114 come from America, 62 from Asia, three from Africa, and one from Australia. Berlin University is therefore in reality cosmopolitan. In addition to the duly registered students there are 5466 persons who are entitled to attend the lectures there; for instance, the students of the technical and other academies and others to whom this right has been granted by a special decree of the Senate of the University. The number of female students is 439.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Mortality and Serum Treatment of Diphtheria in Rome.

A PAPER by Dr. Spolverini in a recent number of the *Policlinico*[1] on the mortality from diphtheria in Rome shows that a remarkable increase occurred last year both in the number of cases and in the death-rate of that disease in this city. The period studied (from July 1st, 1895, to May 31st, 1900) covers the time following the introduction of the serum treatment. During each of the first four years of that period the average mortality was only 16 per cent., whereas previously it had ranged between 60 and 70 per cent. From July 1st, 1899, to May 31st, 1900, however, the cases were much more numerous than in the four preceding years, whilst the death-rate was almost doubled, reaching no less than 28 per cent. To explain such a sudden and exceptional rise various factors must be considered, chief amongst which is the occurrence of previous febrile diseases, more especially of measles. This complaint was indeed very prevalent in Rome from November, 1899, till the end of the following May, and an analysis of the cases treated in hospital during that time shows that out of a total of 56 cases 20 had a history of an attack of measles preceding the diphtheria. Amongst these same cases there were 16 deaths, of which 12 occurred in children who had suffered from measles not long before. The localisation of the false membrane is always a powerful factor in determining a high rate of mortality in diphtheria. This is well seen from the following analysis of the 985 cases notified to the authorities during the years under consideration:—

Localisation.	Cases.	Deaths.	Mortality per cent.
Pharynx	538	78	14·49
Larynx	447	112	25·05

[1] Policlinico, Sezione Pratica, anno vii., fasc. 5.

This cause operated still more fatally in children the resistance of whose tissues had been weakened by preceding attacks of measles, for of the 133 laryngeal cases which occurred between July 1st, 1899, and May 31st, 1900, no less than 44 (33·83 per cent.) were fatal. Over the same period intercurrent acute affections (which invariably swell the rate of mortality in diphtheria) were exactly double the average of the first four years and the death-rate was increased to a corresponding degree. The paper concludes with remarks on the serum treatment, which Spolverini regards as unfailing if employed on the first day of an attack of diphtheria, but as next to useless if delayed until the third or fourth day, as happens only too often in a hospital, to which the most desperate cases are usually sent, very frequently late in the course of the disease. A quantity of serum varying from 3000 to 4000 units was used, and the first signs of improvement were generally noticed after 24 hours from the time of injection. No bad results are attributed to the administration of the serum and in those cases treated early all the patients recovered completely without ever presenting any complication.

Proposed Law for the Prevention of Malaria.

The text of this Bill as drawn up by Celli and others has been published. It consists of five articles, the first of which provides for the official declaration of affected zones, and the second for the gratuitous distribution of quinine to the poor by municipal authorities and the taxation of the property for the purpose of raising the necessary funds. Article 3 makes it incumbent upon the Governmental department or Government contractor responsible for the execution of any public works which give rise to the occurrence of malarial fevers to supply quinine gratuitously, and requires that if any person dies or becomes permanently disabled from malaria whilst employed on such works the same indemnity must be paid as that established for persons under the Employers' Liability Act of 1893. Article 4 enjoins the protection against the entrance of insects to all houses within the malarial zone inhabited by persons employed in the public service and on public works from the beginning of June till the end of December, and offers rewards not exceeding 1000 lire (£40) to proprietors and manufacturers who do the like for the houses of their employés and of the peasants. Article 5 empowers the Government to take whatever further measures may seem necessary for the carrying out of the provisions of the law after such measures have been approved by the Superior Council of Sanitation and by the Council of State.

The Foreign Practitioner Question.

On coming up for discussion in the Chamber of Deputies the Bill proposing amendments in the law regulating foreign practice in Italy, the text of which I gave in my last letter,[2] was, at the request of its sponsor, Dr. Santini, referred back to the Parliamentary Committee which drew it up. On account of the change of Government now taking place a considerable time must elapse before the measure can be reintroduced, and hopes are entertained that it will be abandoned altogether.

Feb. 9th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Elmira Reformatory, New York State.

IN this large reformatory there has been within the past year and a half a complete change in management with a corresponding somewhat radical alteration in the methods pursued. Mr. Brockway, the late superintendent, had been at the head of the institution for a number of years, and although the means followed by him to preserve discipline among and to educate the inmates had for a considerable time been harshly criticised in the lay papers as unnecessarily severe, it must in his favour be said that his results were on the whole satisfactory and met with the general approval of the majority of the medical journals of America. The twenty-fifth annual report of the board of managers has recently been presented to the New York State Legislature, and referring to methods of administration the report says: "The radical difference of views which had existed between the remaining members of the old board

[2] THE LANCET, Jan. 26th, 1901, p. 290.

and those more recently appointed by Governor Roosevelt had made harmony of action impossible and it was not until the beginning of the year 1900 that the latter were able to undertake and enforce the measures for improvement. For a number of years tuberculosis has been an increasing and dangerous feature among our prisoners. Many have it upon arrival in a more or less advanced stage; others develop it under the trying conditions of prison life and association with those already affected. The management further became convinced, by careful scrutiny extending over many months, that prisoners healthy on arrival became affected. There was marked absence in the medical department of our predecessors of full and detailed records both as to cases of ordinary disease and of insanity." Under the head "discipline" the report says: "Since the statement in the last annual report that flogging had been abandoned at Elmira some sincere friends of the reformatory have expressed the fear that its discipline would deteriorate. The board has not shared that fear." The maintenance of the educational system by the present board has been seriously questioned by those who profess to see in the withdrawal of Mr. Brockway the first step towards the destruction of the fabric which he has laboriously created. The board finds in this system much to admire and uphold, something to criticise and modify, and something to condemn. The gross number of inmates who have been on the books during the past 12 months is 2050, of whom 666 were received during that period and 774 were dismissed, producing a daily average of 1365. The efficient control of so large a reformatory is an undertaking which will tax the brains and energies of the most active and intelligent superintendent and staff. It remains to be seen how the new methods will work. The result will be a matter of much interest to philanthropists everywhere.

Dental Surgeons in the United States Army.

The new Army Bill before Congress has the following provision: The Surgeon-General of the Army, with the approval of the Secretary of War is authorised to employ dental surgeons, to serve the officers and enlisted men of the regular and volunteer army, in the proportion of not exceeding one for every 1000 of said army and not exceeding 30 in all. The said dental surgeons shall be employed as contract dental surgeons under the terms and conditions applicable to army contract surgeons, and shall be graduates of standard medical or dental colleges, trained in the various branches of dentistry, and of good moral and professional character, and shall pass a satisfactory professional examination. It is also provided that three of the number of dental surgeons to be employed shall be first appointed by the surgeon-general, with the approval of the Secretary of War, with reference to their fitness for assignment under the direction of the surgeon-general, to the special service of conducting the examinations and supervising the operations of the others, and for such special service an extra compensation of $60 per month will be allowed; also, further, that dental college graduates now employed in the hospital corps, who have been detailed for a period of not less than 12 months to render dental service to the army and who are shown by the reports of their superior officers to have rendered such service satisfactorily, may be appointed contract dental surgeons without examination.

Vaccination in Alaska.

The Yukon Council, the legislative body of the region, has passed an ordinance requiring all persons in Yukon Territory, extending from White Horse to Forty Mile, to be vaccinated as soon as the vaccine arrives. This order affects from 10,000 to 15,000 persons. The Council has appointed the six Dawson physicians to make a house-to-house visitation throughout Dawson and along all the Klondyke creeks and to vaccinate all persons who have not been vaccinated within the last seven years. The Government bears all cost of vaccination under this compulsory order and the operators are paid $30 a day for their services. A mounted policeman will accompany each physician to see that his mission is not abused. Anyone refusing to submit to vaccination will be liable to a fine of $250 or three months in jail, and anyone not reporting a case of rash or anything looking like small-pox will be subject to a much heavier penalty.

Notification of Tuberculosis.

Dr. H. M. Biggs, of the Board of Health of New York City, in a recent address referred to certain English writers who had argued against the notification of tuberculosis, among whom was the late Sir Richard Thorne. To Dr. Biggs it seemed incomprehensible that a tuberculous person should be permitted to live in a crowded workroom where he would be a menace to all about him. Tuberculosis, while it is a highly infectious disease, in his opinion should be put in a class by itself. As to the means of limiting its spread, the best plan is compulsory notification and registration. The New York Board of Health has not classed it as a "contagious disease" but as a "communicable" disease. When a report comes into that department notices are at once sent out to the physician and to the patient giving proper instructions as to preventive measures. Another important thing is that it is not necessary for the general public to be aware that a case of tuberculosis has been reported to the Board of Health; the records are simply for the use of the department. It was from fear of publicity that a strong protest was made against compulsory registration in New York. At this time in New York, where there is compulsory registration, about 10 000 cases are reported annually, excluding duplicates. It has been found that a man suffering from the disease goes from institution to institution, thus being reported as many as 15 or 20 times. City hospitals for advanced cases and country hospitals for incipient cases seem to Dr. Biggs to be the ideal plan.

Jan. 18th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The New Medical Act, New South Wales.

THE first prosecution under the new Medical Practitioners Amendment Act took place at the Central Court, Sydney, on Dec. 28th, 1900, when Charles Saunders was charged that, "not being a legally qualified medical practitioner within the meaning of the Medical Practitioners Act, 1898, or entitled to be registered as a legally qualified medical practitioner within the meaning of the Medical Practitioners Amendment Act, 1900, he did on Dec. 12th use the title 'Doctor,' implying that he was a legally qualified medical practitioner." The proceedings were taken by the police and conducted by the Crown law officers. Evidence was given that suspended from the balcony of defendant's residence in Pitt-street, Sydney, was a lamp with "Dr. Saunders" printed on it, and on the window was printed, "Advice and medicine free." The defendant was not registered and he admitted that he intended the letters "Dr." to mean "doctor," though he was merely a chemist. He was fined £50 and costs with the alternative of a month's imprisonment.—The Council of the New South Wales Branch of the British Medical Association has passed the following resolution with reference to Mr. Meagher, M.P., who took charge of the Medical Act in the Legislative Assembly:—

The council desires to convey to you its high appreciation of your endeavour to improve the legislation governing the relations between the medical profession and the public.

Election of Dr. James Graham as Mayor of Sydney.

On Dec. 13th, 1900, was held the first meeting of the new council of the city of Sydney and one of its first acts was to elect Dr. James Graham as mayor. The Sydney City Council has of late come in for very searching criticism for its lax conduct, especially of the financial and sanitary affairs of the city. A party of reform was instituted which took active measures when the plague broke out, a vigilance committee being appointed to inquire into sanitary defects. Dr. Graham took a very leading part in this reform movement and was chairman of the vigilance committee. In this capacity he gave a great deal of time and labour to the work and roused the civic authorities out of their lethargy. The value of his services to the community in this respect can hardly be over-estimated and it is gratifying to find that they have been rewarded. The new mayor promises to do his utmost for the reorganisation of the health department of the city. The medical officer of health of Sydney will in future be required to give his whole time to the duties of his office with a reorganised and enlarged staff of competent inspectors. The new mayor will also endeavour to conduct the business of the council on more orderly lines and to have the exact financial position of the city made clear. The past career of Dr. Graham both in the profession and in public life is a warrant that he will be successful in carrying out the proposed and necessary reforms. He is a native of Edinburgh and is 44 years of age. He graduated as M.A. and M.D. at

Edinburgh, gaining the gold medal for his thesis on "Hydatid Disease in Australia." He was for some years medical superintendent of the Prince Alfred Hospital and was also on the honorary staff. He is now a director both of the Prince Alfred Hospital and the Sydney Hospital and was the founder of the Women's Hospital. For seven years he has been the Parliamentary representative of the Belmore electorate in the Legislative Assembly. He entered the city council two years ago and, as stated, from the first he was the leader of the Reform party. In his profession he has been very successful and is very popular. His election as mayor has given great satisfaction to the medical profession.

The Sydney and Suburban Provident Medical Association.

Rule 24 of the Sydney and Suburban Provident Medical Association is to the effect that "a general meeting of the profession shall be held once a year to receive a report on the working of the association." Such a meeting was recently held, Dr. P. Sydney Jones presiding. The report showed that the association had met with a fair measure of success and that the working expenses were about 17 per cent. This was a little higher than those of the similar association at Eastbourne, but the large area embraced by the Sydney association increased the cost of working.

Experiences of Australian Surgeons in the South African War.

The Australian surgeons who went to South Africa either as consultants or with the various contingents are now returning and describing their experiences. In the *Intercolonial Medical Journal of Australasia* for December appear two papers, one by Sir T. N. Fitz-Gerald, who went from Melbourne as consulting surgeon, and the other by Mr. A. Honman, medical officer in charge of the second Victorian contingent. Sir T. Fitz-Gerald was appointed to inspect Natal and he gives an account, necessarily brief, of the military hospitals there—at Pietermaritzburg, Mooi river, Estcourt, Ladysmith, and Newcastle. He speaks in the highest terms of the work done both by the Royal Army Medical Corps and the army nursing service, but he says that the instruments supplied to the various hospitals were of a very obsolete kind and reminded him of the antiquated cases provided by economising governments for the emigration service 50 years ago. The only exception was the x ray apparatus, which was complete and very successfully used, though in many cases the results obtained by it in locating bullets were misleading. He narrates several interesting cases that came under his observation. He found generally that wounds healed much better at the camp than at the base hospital, that there was not much difference between the effects of the Mauser bullet at long and short ranges, and that the wounds of entry and exit gave little information as to the extent of the injury. The amount of splintering of bone probably depended upon the angle at which it was struck or was due to an expanding bullet, the apex of which had been purposely divided. Mr. Honman also discusses in some detail the effects of the Mauser bullet at different ranges and quotes a number of cases to show the extreme diversity of the nature of the injuries inflicted, especially on bones. The chief impression left was "that however shattered a bone may be it may marvellously recover" and that the conclusions as to the effects of bullets derived from experiments on dead bodies had not been borne out by actual results. As a regimental surgeon whose duty it was to follow on with the troops he had not much opportunity of watching the progress of wounds, but of those he did see few went wrong. The first-aid dressing that every soldier carried with him, gauze, gauze tissue, and jaconette, was sufficient for most cases, and it was astonishing how quickly wounds healed and how soon wounded men rejoined their regiments. Dr. A. MacCormick of Sydney, who went with the New South Wales Army Corps, has just returned. He accompanied the troops *viâ* Stormberg to Bloemfontein, where the corps was divided and Dr. MacCormick with half a company joined the troops under Ian Hamilton *viâ* Kroonstad and Lindley to Heilbron and then to Pretoria and Diamond Hills. He was several times under fire, but he says that enteric fever was far more disastrous to the troops than was the enemy. Major Fiaschi, who was with the New South Wales Army Medical Corps No. 1 Field Hospital, has also returned to Sydney and speaks in the highest praise of the men of his corps, who have been nearly all the time under fire since they arrived at the front twelve months ago. The corps was first sent to the Orange river and then accompanied Lord Roberts's column up to the Modder, Jacobsdal, and Paardeberg. They were present at the storming of Cronje's laager and at the battles of Poplar Grove and Abram's Kraal. They were in the advances on Johannesburg and Pretoria, then to Middleburg, where they got the worst cases from General Buller. Finally they accompanied General Hutton to Kaafsche Hoof and then retired to Heidelberg. Major Fiaschi considered the New South Wales Field Hospital as good as any in the war, but its equipment was not sufficient and the military orders want remodelling. If the surgeons had not taken their own instruments with them many an operation would have been unsuccessful or impossible. Major Fiaschi was personally complimented by Lord Roberts at Bloemfontein, and General French spoke in warm eulogy of the services of the New South Wales Army Corps.

Perigastric Adhesions.

Mr. Fred. D. Bird contributes a long and interesting paper to the *Intercolonial Medical Journal* for December on the subject of Perigastric Adhesions, dealing, not with the denser forms to which attention has been drawn by others, but to very slight forms which are apt to be overlooked in an operation unless the operator specifically searches for them. Some are secondary to healed gastric ulcer, but most, he believes, are in the neighbourhood of the bile-ducts, due to a cholangitis from bacterial infection. The adhesions are not dense and widespread but thin and wiry. The main symptom is epigastric pain, started or increased by food and not relieved by medical treatment. Mr. Bird quotes a number of cases in support of his views.

Successful Suturing of the Ends of a Destroyed Median Nerve to the Ulnar Nerve.

In the same number of the *Intercolonial Medical Journal* Dr. W. Moore records a very interesting case. A boy aged 14 years was admitted to the Melbourne Hospital suffering from a gunshot wound of the forearm which exposed the flexor muscles, while the median nerve was seen as a dark cord on the wound surface and sensation in the fingers supplied by it was completely gone. Ten days after the injury four inches of the exposed nerve separated as a slough. Five weeks after the injury, when the wound was a uniform granulating surface, an operation was undertaken for the repair of the nerve. The two ends of the median nerve were dissected free and the ulnar nerve was then exposed at the wrist and at the upper part of the forearm. The divided ends of the median nerve were freshened, the sheath of the ulnar nerve was opened opposite them, and the ends of the median were attached to the ulnar by fine catgut passing through the whole thickness of the median and through a few fibres of the ulnar, and by catgut sutures bringing the sheaths of the nerves into accurate apposition. The surface of the wound was covered by a skin flap from the upper abdomen against which the arm was fixed. A month later the wound was soundly healed and sensation had returned in the parts of the hand supplied by the median.

Jan. 10th.

Obituary.

LESLIE OGILVIE, B.Sc., M.B. EDIN., M.R.C.P. LOND.

THE death of Dr. Leslie Ogilvie, which took place at his house in Welbeck-street on the evening of Feb. 2nd, must have come as a painful shock to his numerous friends, many of whom had seen him apparently as strong and vigorous as usual only a few days before. He first became ill on the morning of Sunday, Jan. 27th, and symptoms of pneumonia of a peculiarly sthenic type soon became manifest. It was no doubt on account of his fine bodily health and his strong constitution that he was able to maintain the fight against the disease as long as he did.

Leslie Ogilvie was born in Glasgow in 1853, the son of a man remarkable even in Glasgow for his energy and enterprise and no less for his high standard of business rectitude. He was educated at Gilbertfield House, Hamilton, and at the High School of Glasgow, and he went to Edinburgh University in 1868. He was keenly interested in natural science and at first devoted himself to this and took his B.Sc. degree. He was particularly fascinated by geology, then taught in Edinburgh by Mr., now Sir, Archibald Geikie, his favourite professor, and ever since a most cordial friend. Like so

many men who, in those days especially, went to Edinburgh with other views, he was caught in the vortex of medical interests and drawn into the curriculum. He took excellent places in his classes and during one session he acted as prosector in anatomy to Professor (now Sir William) Turner. Still maintaining his interest in natural history he also at this time dissected a shark to illustrate Professor Turner's monograph on the Elasmobranch fishes. After taking his medical degree in 1876 he studied in Paris for a time but returned to Scotland to act as locum tenens for Dr. David Stirling of Perth, one of the best known and most highly esteemed practitioners in Scotland. He afterwards went abroad for two years, studying in Vienna and elsewhere, acquiring a good knowledge of French, German, and Italian, languages from which he subsequently derived much literary pleasure. He came to London in 1879 and commenced practice. Very soon after his arrival he, along with Dr. G. L. Laycock, Dr. Colcott Fox, and others, became interested in a somewhat languishing dispensary then known as the Bell-street Dispensary for Children. Thanks to their combined labours it soon became so much appreciated that it seemed justifiable to associate beds with the out-patients' work and it was converted into a hospital, the now well-known Paddington-green Children's Hospital, of which he was senior physician at the time of his death. For many years he devoted much time and energy to his work here, and those who knew his cordial and genial manner will understand how much his work was valued both by patients and colleagues. Latterly his chief interest was in insurance work. He was medical referee to the Standard and Scottish Life Companies and a paper read by him a few years ago before the Edinburgh Society of Actuaries is one of the most thoughtful and important contributions to the medical aspects of life insurance in recent years. He became M.R.C.P. in 1889, and two years ago was elected a member of the Athenæum Club. His social gifts imposed many duties upon him. For nearly 15 years he was a most popular secretary of the Edinburgh University Club of London, and he was for several years President of the Burns Club. He was married a few years ago and leaves a widow and three children.

Such was Leslie Ogilvie's career as it appeared to the public. To a large circle of friends, however, he was much more than such a bare outline would seem to indicate. His was one of those rare fine natures which attract to themselves the devoted affection, one might almost say the love, of those who know them well. It was not only that he was genial, kind-hearted, and open-handed almost to a fault, but he possessed also that singular personal attractiveness which attached to him in a peculiarly close way those who knew him well and induced mere acquaintances to enrol themselves in the ranks of his friends. He was fond of music and literature, especially poetry, and he had a peculiarly fine literary instinct which a busy life left him too little opportunity of exercising. He was also fond of outdoor amusements; for many years he was an ardent member of the London Scottish, and up till the last a keen and good golfer. Such are but a few of the facets of a many-sided and lovable nature. His death will be deeply mourned by many who knew him only slightly; to those who knew him well it is nothing less than an irreparable calamity.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND: EXAMINATION FOR REGISTERED PRACTITIONERS.—Mr. Thomas Blanchard Sellors, L.S.A. Lond., having passed the necessary examination has been admitted a Licentiate in Surgery of the College.

METHODS OF VACCINATION.—At the meeting of the Devonport Board of Guardians held on Feb. 4th it was decided, upon the suggestion of the Vaccination Committee, to draw the attention of the Local Government Board to the fact that a private medical practitioner might legally vaccinate a person in one place only and certify that such person had been successfully vaccinated, whereas a public vaccinator must vaccinate in four places. The guardians consider that a child ought to be vaccinated in more places than one, and they therefore urge the Local Government Board to endeavour to get the law altered.

BATH ROYAL UNITED HOSPITAL.—Through the liberality of two members of the committee of this hospital a bacteriological laboratory has been added to the institution.

FROM a return presented at the last meeting of the Leicester Board of Guardians it appears that during the year 1900 there were 446 cases of successful primary vaccination in the borough as against 219 for the year 1899.

MEDICAL SERVICES APPRECIATED.—At a meeting held on Feb. 7th of the Stratford-on-Avon Board of Guardians, Mr. C. Couchman (the vice-chairman) proposed a motion, which was unanimously adopted, tendering grateful thanks to Mr. James Arthur, M.R.C.S., on his resigning the post of medical officer and public vaccinator of the Wootton Wawen district of the union, after 35 years' efficient performance of the duties attached to the office.

A HANDSOME BEQUEST.—Probate has been granted in the Gloucester Registry of the will of the late Mr. John William Ormond Howes, a retired Cheltenham tradesman, who died about a month ago and whose estate has been proved at just under £14,800. After payment of personal bequests to the executors, solicitor, and housekeeper, amounting to £1200, the residue is bequeathed to the Cheltenham General Hospital, which will receive the net sum, after payment of legacy duty, of about £11,500.

UNIVERSITY OF CAMBRIDGE.—Dr. A. W. Ward, Master of Peterhouse, has been elected a member of the council of the Senate.—Professor A. Macalister has been appointed an elector to the chair of Chemistry, Professor Newton an elector to the chair of Anatomy, Professor R. Liveing an elector to the Downing chair of Medicine, Dr. F. Darwin an elector to the chair of Zoology and Comparative Anatomy, Dr. Pye-Smith an elector to the chair of Physiology, Dr. D. MacAlister an elector to the chairs of Surgery and of Agriculture, and Professor Allbutt an elector to the chair of Pathology.—Mr. Clinton T. Dent has been appointed an Examiner in Surgery in the place of Professor Chiene, resigned.—Caius College will elect to a Shuttleworth Scholarship in Botany and Comparative Anatomy, value £55 per annum for three years, next March. Candidates must be medical students of the University of at least eight terms' standing. Applications are to be sent to the senior tutor before March 2nd.—At the congregation on Feb. 14th, Mr. E. S. Verdon, M.A., M.B. Cantab., was admitted to the degree of M.D. *in absentiâ*. Dr. Verdon is resident at the Court of Morocco.

LEICESTER BOROUGH ASYLUM: OPENING OF NEW BUILDINGS.—On Feb. 8th the extensive new buildings of the Leicester Borough Asylum, which, exclusive of the land, have been erected and furnished at a cost of £94,743, were formally opened. The extension, which is to the east of the old buildings and comprises a complete asylum for males, provides accommodation for 335 patients. The total number of beds now provided in the whole institution is 855, which is greatly in excess of the present requirements of the borough. In the meantime the surplus accommodation will be used by outside patients and will, it is hoped, prove to be a source of revenue to the institution. From an exterior point of view the new extension presents no striking features, the severe red brick being relieved by a dressing of stone only. The wards have been arranged in blocks in echelon, but as a continuous building, with a main corridor in the rear, giving a separate approach to each ward. The formation of the site, which slopes considerably to the south, made this arrangement necessary, and as a result the whole of the wards face the south and receive much more sunshine than would otherwise be the case. The wards have a bright and cheery appearance and are lofty, well lighted, well ventilated, and comfortably furnished. The recreation hall, in which a weekly entertainment will be given to the inmates, is a very fine building with a stage at one end and dressing and property rooms and other accessories for theatrical performances. The administrative buildings have been excellently arranged and include a spacious and handsome committee-room. The whole of the buildings are heated by steam on the most approved principle and electrically lighted throughout, the total cost of the installation for the latter being no less than £4000. The buildings are also fitted with fire-alarms, and by a most ingenious tell-tale clock the superintendent will be able to

see at what hour the wards and dormitories are visited by the attendants, each visit being automatically registered by the clock. The plans for the extension were prepared by Mr. Hine of London, consulting architect to His Majesty's Commissioners in Lunacy, and Messrs. Moss and Sons, Limited, of Loughborough, secured the building contract, the work being commenced in the autumn of 1897. The old asylum, with its administrative block, was built to accommodate between 300 and 400 patients, and that the institution has not been extended much too soon is evidenced by the fact that the number of patients is now no less than 576. The opening ceremony was performed by Alderman Dr. Clifton, the chairman of the asylum committee, in the presence of the mayor and corporation and representatives of the local public bodies.

Births, Marriages, and Deaths.

BIRTHS.

HEWLETT.—On Feb. 7th, at Lyddon House, Southfields, S.W., the wife of R. Tanner Hewlett, M.D., M.R.C.P., of a son.

KENT.—On Feb. 11th, at Holland House, Paignton, S. Devon, the wife of R. T. Kent, M.A. Oxon., F.R.C.S., of a son.

REID.—On Feb. 5th, at Broc Hill, Milford, Stafford, the wife of George Reid, M.D., of a son.

VOELCKER.—On Feb. 9th, at Harley-street, the wife of Arthur Francis Voelcker, M.D., F.R.C.P., of a son.

MARRIAGES.

ROBERTSON—HOLL—On Feb. 7th, at St. Alban's, Acton-green, on Jan. 31st, by Rev. Bernard Spink, W. J. Robertson, M.R.C.S. Eng., L.R.C.P. Lond., eldest son of W. Robertson, M.D., of Glanton House, Northumberland, to Theodora, eldest daughter of W. J. Holloway, Esq., of Mia Gunyah, Bedford Park, W. No cards.

TALBOT—GIBSON.—On Feb. 6th, at St. George's, Bloomsbury, Alfred George Talbot, M.B., M.S. Edin., of Richmond, Nelson, New Zealand, to Beatrice Esther, second daughter of Frederick Denhame Gibson of Christchurch, New Zealand.

WHITE—MEGRET.—On Feb. 12th, at the Roxburghe Hotel, Edinburgh, T. B. White, M.B. Edin., Moffat, to Constance, daughter of Adolphe Mégret, No. 68, Rue de Grenelle, Paris.

DEATHS.

BARNETT.—On Feb. 6th, at The Brook House, Leominster, Herefordshire, Samuel Barnett, M.R.C.S., J.P., aged 80 years.

BAYLEY.—On Jan. 12th, at Johannesburg, Richard King Bayley, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., second son of W. H. Bayley, solicitor, Basingstoke, aged 30 years.

CULBARD.—On Feb. 9th, at Dunkeld, John C. Culbard, M.D., M.R.C.S.

JONES.—On Feb. 11th, at Sheep-street, Northampton, Arthur Henry Jones, M.D. Lond. aged 48 years.

RUGG.—On Monday, Feb. 11th, at Avenue Lodge, Wood Green, Baron Alfred Rugg, L.R.C.P. Lond., M.R.C.S., aged 53 years.

SCRATCHLEY.—On Feb. 6th, at Pelham House, Poole, Dorset, Henry William Scratchley, L.R.C.P., M.R.C.S., aged 38 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE FEES OF A MEDICAL WITNESS.

MR. JUSTICE RIDLEY allowed himself to speak in terms almost of stricture because a consultant medical man demanded 20 guineas for giving medical evidence. The witness explained that to attend the court was a serious inconvenience, and that evidence might well have been given by a practitioner whose time was, perhaps, not so valuable. Mr. Justice Ridley would find it difficult to explain why, in these circumstances, there was anything extortionate or even inconsiderate in the price fixed by the medical witness for his services. Practising barristers could tell his lordship stories of the fees demanded and exacted by experts in other provinces of art and science that would make the 20 guineas asked by the medical expert seem boundlessly moderate.

MEDICAL SUPERSTITIONS.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers recommend me a book to refer to for a popular lecture on medical superstitions? Thanking you in anticipation,

I am, Sirs, yours faithfully,

Feb. 11th, 1901. M.B. LOND.

*** We take it that our correspondent requires literature on superstitions connected with medicine. Almost any book on folk-lore will give him information on the subject—e.g., Henderson's "Folk Lore of the Northern Counties of England." Gould's "Anomalies and Curiosities of Medicine" will also help him, and a mine of wealth as to drugs and the medicinal properties of animals is to be found in "The History of Four-footed Beasts," by Topsell, a sixteenth-century writer. If our correspondent has time he might study the works of Sir Thomas Browne and Sir Kenelm Digby. Anti-vaccination literature will also be found fruitful, especially in its early days when it was stated that any child who was vaccinated developed horns and a tail. Perhaps some of our readers can suggest other works of reference.—ED. L.

A MISTAKE SOMEWHERE?

To the Editors of THE LANCET.

SIRS,—Surely the report of Lord Lister's speech at the York-road, Lambeth, Hospital as it appeared in the *Standard* cannot be correct. Speaking of certified midwives, he is credited with these words in *oratio obliqua*: "The inmates of that institution are far better off than the middle classes who had to trust to the 'general practitioner,' who hitherto had not, on the average, been persuaded of the enormous importance of antiseptic precautions."

I am, Sirs, yours faithfully,

Feb. 6th, 1901. H. W.

LANTERN SLIDES FOR THE PASSION PLAY.

To the Editors of THE LANCET.

SIRS,—Your correspondent "G. P.," who asks in THE LANCET of Feb. 9th, p. 444, where he can obtain slides, &c., for a lecture on the Oberammergau Passion Play, can purchase a lecture and hire slides from E. G. Wood, 1 and 2, Queen-street, Cheapside, E.C. The slides, however, illustrate only the performance of 1890, not that of 1900; slides of the latter are very expensive.

I am, Sirs, yours faithfully,

Feb. 8th, 1901. J. W. C.

"CHRONIC DIARRHŒA: SUGGESTIONS FOR TREATMENT DESIRED."

To the Editors of THE LANCET.

SIRS,—In reply to "Perplexed" the chronic diarrhœa may be due to want of complete evacuation of the bowels in an aged person. I suggest enemata of warm injections with oil and some turpentine twice or thrice a week. The diarrhœa may yield to the following: one and a half ounces of sulphate of magnesia and one ounce of sulphate of soda; mix, take a teaspoonful in half a tumbler of hot water every morning before breakfast. It might be well to explore the rectum.

I am, Sirs, yours faithfully,

Jan. 29th, 1901. LIEUTENANT-COLONEL, R.A.M.C.

H. M. W. D. writes:—I should be glad of suggestions as to cause and treatment in the following case. The patient, a lady, married, aged 40 years, no children, suffers from what she well describes as uncontrollable fidgets. The attacks come on every evening with more or less severity; the disturbance is in the lower limbs only and begins with pain and tingling; she is quite unable to keep the limbs quiet or sit still; the condition passes off during the night. The trouble has existed for some years, but is becoming much worse and is a source of distress to herself and friends. A sister and brother deceased were affected in the same way. The condition causes insomnia. The patient leads an active life, takes much exercise, and has good digestion. There is chronic constipation, which at one time occasioned a serious obstruction; there are slight varicose veins and many dilated venules on the legs. The slightest injury produces extensive ecchymosis. Is the condition due to toxic or mechanical effects of constipation? It is not relieved by ordinary laxatives. Or is it a nervous condition and beyond treatment?

Dr. H. J. Gardiner.—The question of medical certificates for a school board is a thorny one. For various points connected with the subject we would refer our correspondent to THE LANCET, vol. ii., 1895, pp. 48, 165, *et seq.*; to vol. i., 1896, pp. 1511, 1808, 1823; to vol ii., 1896, pp. 259, 330, *et seq.*; and to vol. i., 1897, p. 331. The chief points to be noted are these. A school board has no right to demand a medical certificate, but it has a right and a duty to see that children attend school. If the parents or guardians of the children cannot show a reasonable excuse the board can summon them and the magistrate can demand a certificate. The medical man can, if he likes, give a certificate gratis, or he may prefer to attend the police-court and give evidence on behalf of the child.

A. R. perceives, as no one can help perceiving, the possible awkwardness of the position. We strongly advise him to avoid the appearance of connexion with an unqualified dentist that must follow upon the use of a common room on the same premises. No enalty can follow if he can prove that he has clean hands, but why incur the chance of a complaint being made to the General Medical Council?

J. H. H.—1. In our opinion the whole club should subscribe for a medical man. The fact that many of the members belong to other clubs does not free them from the obligation of helping to support a medical man for the benefit of their fellow-members who do not belong to other clubs. 2. Not less than 1½*d.* per head per week.

Enquirer.—We have never heard of "Zox" powders. From the label it would seem that they are ordinary quack remedies advertised to cure all sorts of things of different origin. A specimen of the powders can be sent for analysis. 2. We do not know what "Tatcho" is or what claims are made for it in the advertisements.

Luson.—The graduate in question may be somewhat improperly described in the paper. But there is no reason to suppose that he wrote the paragraph himself, and the editor of a lay journal cannot be asked to observe the minutiæ of medical titles. Who, then, are we invited to put the blame upon?

M.R.C.S. (1).—The communication is founded upon a misreading of our article.

M.R.C.S. (2).—We will endeavour to be of assistance.

G. A. F. should disregard the matter entirely.

Ward should consult his medical man.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.). Cancer (2 P.M.)

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (18th).—SOCIETY OF ARTS.—8 P.M. Mr. W. J. Pope: The Bearings of Geometry on the Chemistry of Fermentation. (Cantor Lecture.)

TUESDAY (19th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Dr. W. P. Herringham: On the Condition of the Renal Arterioles in Cases of Chronic Renal Disease (lantern demonstration).—Dr. A. G. Auld: Additional Remarks on the Toxins of the Pneumococcus.—Mr. R. Johnson: Congenital Atresia of the Vesical Orifice in One Ureter with Prolapse of its Dilated Extremity through the Urethra.—Dr. W. C. Bosanquet: Multiple Inflammation of Serous Membranes in Children. Card Specimens:—Mr. C. Keep: Pyronephrosis.—Mr. Drew: Double Renal Calculus.
CHELSEA CLINICAL SOCIETY (Holy Trinity Parish Hall, Pavilion-road, Sloane-square, S.W.).—8.30 P.M. Papers:—Mr. F. C. Abbott: Spinal Curvature and Physical Exercises (with demonstration).—Dr. C. J. Harrison: Acute Rheumatism of Childhood.

WEDNESDAY (20th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. Mr. C. Beck: Exhibition of Bacteria and Blood Parasites.

THURSDAY (21st).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Clinical Evening.
CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Exhibition of Clinical Cases followed by discussion. Patients will be in attendance from 8 P.M. to 9 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. J. Pringle: Consultation. (Skin.)
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Mr. W. Edmunds: The Pathology and Diseases of the Thyroid Gland. (Erasmus Wilson Lecture.)
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. A. Willey: The Origin of Vertebrate Animals.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Moullin: Gynæcological Cases.

TUESDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Consultation. (Medical).

WEDNESDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Clinical Lecture:—Sir J. B. Tuke: Insanity a Symptom of Organic Disease.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Mr. W. Edmunds: The Pathology and Diseases of the Thyroid Gland. (Erasmus Wilson Lecture.)
LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—5 P.M. Dr. F. Potter: Hoarseness and Aphonia. (Post-graduate Course.)
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—3 P.M. Dr. Fowler: The Treatment of Cardiac Failure in Aortic Regurgitation.

THURSDAY (21st).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Dr. D. Grant: Treatment of Nervous Disorders of the Pharynx and Larynx.
CHARING-CROSS HOSPITAL.—4 P.M. Dr. A. Routh: Gynæcological Demonstration. (Post-graduate Course.)
MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—3 P.M. Dr. H. Low: Class. Roentgen Rays. 4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)
THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. F. E. Batten: Cerebral Diplegias in Children.
THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration:—Dr. P. S. Abraham.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. C. B. Keetley: Surgery of the Joints.

FRIDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Consultation. (Ear.)
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Mr. W. Edmunds: The Pathology and Diseases of the Thyroid Gland. (Erasmus Wilson Lecture.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Clinical Lecture

ON

A QUIET EFFUSION INTO THE KNEE-JOINTS OCCURRING IN WOMEN AND YOUNG GIRLS.[1]

Delivered at St. George's Hospital

BY WILLIAM H. BENNETT, F.R.C.S. ENG.,

SENIOR SURGEON TO THE HOSPITAL; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS OF ENGLAND, &C.

GENTLEMEN,—I am anxious to-day to call your attention to a very interesting condition of the knee-joint about which I do not think there is anything to be found in your text-books; it is, however, not uncommon, and as it is from a practical point of view of importance it is naturally worthy of some consideration. The condition is, so far as I can judge, one of passive effusion into the joint; it rarely occurs in any other joint than the knee, although I have seen it on one occasion in the ankle. The joints of the opposite sides are usually involved at the same time, but the effusion is, as a rule, much more marked on one side than on the other, that on the right side being generally the greater. There is rarely any pain unless some injury has been received; beyond a feeling sometimes of weakness there is nothing to attract attention to the matter—indeed, a considerable percentage of those who suffer from the complaint are unaware of its existence unless attention is called to it accidentally. It is limited to girls and women and is always associated with menstrual irregularity or uterine trouble. It occurs mainly at two periods of life—viz., at the time of puberty, when the catamenial affairs are establishing themselves, and at the climacteric time when menstruation begins to cease. It may, however, occur at any intermediate period if there is menorrhagia, excessive hæmorrhage from the uterus, or great irregularity and difficulty in connexion with the menstrual affairs.

My attention was first attracted to this affection some years ago when I met with several cases of painless and unnoticed effusion into the knee-joints of girls of 12 and 13 years of age; and I found upon examining a number of girls who were attending as out-patients at St. George's Hospital that a certain number had painless swellings of the knees of which they and their parents were unaware. In all these cases there was delayed onset of menstruation. Upon inquiry it was found that in some of them, although neither the children nor their parents were aware of anything being wrong, the children tired easily and in some cases were prone to fall down or "double" up without any obvious cause. The character of the joint is peculiar; although containing a considerable amount of fluid it is never tense excepting after superadded injury. The fluid, if the patient is standing, sinks to the lower part of the joint cavity and sometimes leads to a pouch-like overhanging of the synovial membrane at its lower anterior aspect.[2] In the older subjects the aspects of the condition are similar, the main points being the absence of tension and heat and the freedom from pain. The patients are usually anæmic but not invariably so.

As already mentioned, the common cause of the discovery of the condition is an injury, generally very slight, such as a twist or fall; the occurrence of an injury and the existence of effusion naturally lead to a diagnosis of traumatic synovitis, which being apparently of a very chronic nature and occurring in subjects of a delicate type is sometimes mistaken for tuberculous disease, a mistake of some importance. Any error in diagnosis can usually be avoided by noticing the character of the swelling, the existence of effusion on both sides (that on the uninjured side being painless and without heat), and the coincidence of marked menstrual or uterine trouble.

In accordance with my usual custom in these lectures let me bring to your notice the following practical illustrations of the condition of which I am speaking, because, as I have often mentioned to you before, a characteristic case of any kind affords a much more perfect picture of the true aspect of things than abstract descriptions, even if they be perfect in their way.

CASE 1.—A girl, aged 14 years, was brought to me who a few months previously whilst walking across the room had knocked her knee against a chair. She complained of nothing at the time of the injury, but on the following day, as she seemed to walk a little lame, her mother noticed that the right knee was held rather stiffly. Upon examination she found it swollen but not tender. Professional advice was sought and effusion into the knee was diagnosed. The usual treatment by rest was adopted for some weeks without any material benefit. Further advice was therefore taken, a somewhat grave opinion being expressed in respect to the possibility of the case being tuberculous, and I was assured that this opinion was given without a previous examination of the opposite knee. Whether this was really so or not I cannot of course say, but at all events further treatment on the lines previously adopted produced no good result. Later I saw the patient with her medical attendant and upon investigation found that both knees contained a good deal of fluid; neither joint was tense but on the contrary was rather flabby; there was no pain or tenderness; the local temperature on the side which had been injured was, however, certainly rather more than on the other. The girl was anæmic and of a delicate aspect. She had not yet menstruated, but certain pains and symptoms of irritability clearly indicated that menstrual developments were tending to come about. Under the circumstances, judging by my previous experience of similar cases, I ventured to predict that the trouble would subside upon the establishment of the catamenial function and advised the discontinuance of rest and splinting, which had made the injured joint already somewhat stiff, substituting exercise and massage, with as much fresh air as possible. The menstrual affairs, although much delayed, occurred later with great profusion. From the moment of the onset of the catamenial discharge improvement commenced and at the end of a fortnight after the second catamenial period the knees were both entirely normal and remained so subsequently.

CASE 2.—A well-developed woman, aged 24 years, met with a slight injury to one of her knees. She took little notice of the injury, but on the following day, upon getting up in the morning, she noticed some stiffness in the injured knee, and upon examination found it swollen. For a fortnight, as the discomfort was but slight, no further attention was paid to the matter, but then, as the swelling persisted, a surgeon whose name were I to mention it would be a sufficient guarantee of his capacity was consulted. He took a rather serious view of the condition and urged immediate splinting of the part and rest in bed for at least a month. As the patient was one of those people who live in the open air—hunting, golfing, &c.—this recommendation was regarded with dismay, especially as beyond the swelling little or no discomfort was present. She was then brought to me as an alternative opinion. Upon examination the left knee was considerably swollen from effusion; it was not tense. In the erect position the synovial membrane tended to drop forwards and to overhang the part below the joint. Beyond a feeling of slight stiffness, which was not enough to produce anything like a noticeable limp, the symptoms were negative. The opposite knee also contained fluid which, although not obvious when the patient was sitting in a chair, became at once manifest in the standing position. This knee had received no injury nor was the patient aware of the existence of the fluid; indeed, she was certain that the injured knee was also free from fluid before the injury, this being clearly an error on her part. Upon inquiry it appeared that her menstrual affairs had always been irregular and very painful and at the time of her coming to see me she had not menstruated for two months, although at the last normal date she had felt ill and irritable and suffered from distressing bearing-down pains. Judging from the general aspect of the case I came to the conclusion that it was one of the kind now under observation. I therefore felt compelled, in spite of the opinion already given, to oppose the use of splints and rest in bed, the latter of which seemed to me

[1] The Lecture is published as it was delivered excepting the omission of some elementary details which would here be superfluous.

[2] It may be pardonable to remark here that a small quantity of fluid in the knee-joint which when the joint is flexed or if the patient is lying down can only be detected by very expert observers becomes quite obvious on placing the patient in the standing position.

likely to be extremely disadvantageous to a patient of such habits and disposition as this one possessed. I therefore recommended massage, moderate exercise in the open air as much as possible, and the resort to some obstetric authority with a view to the rectification of the menstrual defects. Two opinions so exactly opposite naturally necessitated the reference of the case to a third surgeon, a man of eminence and great discretion, who, adopting very wisely a strictly judicial attitude, declined to commit himself unreservedly to either view, but went so far as to say that confinement to bed in a temperament like that of the patient was to be avoided if possible. The treatment on the lines of my opinion was therefore adopted, and with the onset of regular menstruation, which happily followed a little later, the knee trouble entirely disappeared, although it recurred temporarily before two successive menstruations.

CASE 3.—This patient was in St. George's Hospital under the care of Dr. W. R. Dakin. She was a married woman, aged 26 years, who was admitted on July 8th, 1898. Since her first confinement, six years previously, she had suffered at menstrual times from great abdominal pain. The catamenia had been extremely profuse and exhausting. For two or three years she had been continually ailing, and latterly any attempt at getting about or doing her ordinary work caused intense malaise. For 18 months the knees had been "stiff and hot" before the menstrual times, but she had noticed no swelling either of the knees or of the legs. On admission the patient was found to be anæmic and she seemed ill. There was tenderness over the right ovary on deep pressure. The right knee, she said, was stiff and uncomfortable. There was considerable effusion in the joint which was, however, flaccid—not tense; there was neither tenderness nor any increase of local heat. The limb below was perfectly normal. The opposite knee contained also a little fluid. On July 16th the effusion in both knees had subsided a little; on the 18th it had increased considerably; and on the 19th profuse menorrhagia with large clots and much pain occurred. Considerable hæmorrhage continued, being profuse until the 27th when it diminished somewhat. The effusion in the knees during this time rose and fell from time to time; sometimes it was slight, sometimes great, but at no time did the joints on either side become tense nor was any other joint than the knee involved. On August 8th the uterus was curetted; on the 10th all hæmorrhage ceased, and by the 19th both knees were perfectly normal. The patient reported herself for examination on Oct. 1st and she was then perfectly well; the knees had given no trouble of any kind and upon examination they were found to be normal in all respects. A more conclusive case than this it would be difficult to find.

CASE 4.—A married woman passing through the climacteric period wrenched her right knee in getting out of a cab. The injury was very slight and she thought nothing of it until the following day, when on rising from her bed in the morning she found the knee a little stiff and upon inspection saw that it was considerably swollen. She therefore sought advice. On examination the knee was found to be swollen and it contained a considerable amount of fluid; the joint was not in any sense distended—on the contrary, the capsule was rather flaccid; the fluid in the standing position gravitated to the lower and anterior aspect of the joint, causing some slight "sagging" of the kind which I have previously referred to. The other knee contained almost as much fluid and presented the same characteristics as the injured joint. Of the existence of anything abnormal on the uninjured side the patient was entirely unaware until it was pointed out to her. On inquiry she then stated that the "change of life" had commenced about six months previously, and at times very free loss of blood had happened; after these considerable losses she now remembered that she generally felt very tired upon much exertion, and that on two occasions she had felt a tendency when walking for her knees to "give way." Of this she thought nothing, as she attributed it merely to weakness from pain and loss of blood. She was kept under observation, and during the whole of the climacteric period, which extended over about 18 months, the knees contained fluid, sometimes a little and sometimes quite a large quantity. The increase in quantity usually, but not always, followed increased pain or extra blood flow. The fluid could be almost entirely removed at any time by a week's massage, but it immediately recurred upon the cessation of the treatment. At the end of the climacteric period both joints became normal, and they have never shown any indication of recurrence of the effusion since. The noteworthy points in this case, as in the others, are: (1) the escape of the condition from observation until attention had been attracted to it by injury; (2) the almost rhythmical rise and fall in the quantity of the effusion; (3) the absence of tension in the joint which was replaced by the peculiar flaccidity; and (4) the spontaneous return to the normal state upon the subsidence of the uterine irregularities.

It is hardly necessary to weary you with descriptions of further clinical examples excepting one (Case 5) very briefly in order to show how important a knowledge of these cases may be.

CASE 5.—The patient was a girl, aged 14 years, who was suffering from the troubles which sometimes arise at that period of life from delayed or painful menstruation. After a slight injury the right knee was found to be swollen considerably. Prolonged splinting with complete rest failed to affect the condition in any noticeable way; the child, on the other hand, began to fail in health from confinement to the house and want of exercise. It was then found that the opposite knee contained fluid in considerable quantity, and it was thought that this effusion in the hitherto sound knee was sudden. The onset of the menstrual period was imminent; the knee was rather hot to the touch, and the temperature was 101° F.; at times the girl felt "shivery" but had no actual rigor. The question therefore arose as to the possibility of the apparently sudden effusion into the knee being a secondary pyæmic condition or something of that kind. There appeared to me no doubt, however, that the case was one of the sort under discussion and that the febrile and general disturbance was merely due to catamenial causes. The case was treated on this supposition; splints were omitted, massage and exercise in the open air as much as possible being substituted. Immediate improvement followed and with the gradual spontaneous rectification in the menstrual irregularities, which ensued in the course of 18 months, the knee trouble entirely disappeared. It is obvious in this case that the knowledge of the occurrence of these conditions was of vital importance for the proper treatment of the patient.

I am unfortunately unable to say how many cases of effusion into the knees of this kind I have seen, for of the earlier cases I kept no memoranda; during the past four years, however, I have seen 20 typical examples in all of which the trouble had been attributed to wrong causes. In three cases I withdrew fluid from the knee by means of an exploring needle; in two of these the fluid was ordinary synovia, in the other it contained a considerable amount of blood. Whether this was an accidental occurrence or whether it had any pathological bearing upon the mechanism of the effusion I cannot say. In only one case have I seen the effusion occur in any other joints than the knees; in the exception mentioned effusion occurred into the left ankle in a very rheumatic subject. The causes assigned for the condition were in order of frequency, injury, tubercle, rheumatism, hæmophilia, and "blood poisoning." In no case did recovery occur when the uterine or catamenial irregularities continued; in every case, on the other hand, so far as my memory serves me, correction of these irregularities, whether spontaneously or by treatment, was followed by complete disappearance of the tendency to effusion into the knees.

Some of you may at this stage naturally begin to speculate as to the practical bearing of these cases which I have related. The practical bearing of the cases is of much moment in diagnosis, treatment, and prognosis. First, with regard to—

Diagnosis.—When called upon to examine a case of a woman or girl suffering from painless effusion into the knee, especially if she be at the period of the onset of the catamenial flow—i.e., from the ages of 11 to 14 years—or at the climacteric, never omit to inquire into the state of the uterine functions, and never omit the ordinary surgical routine of examining both knees although the patient may ascribe the effusion to a distinct injury of only one of them. If there be the functional irregularities to which I have referred you will as a rule find fluid in both knees, generally in excess on the right side, and although the patient may be convinced that the condition is due to recent injury it may be concluded for purposes of treatment that the injury is only an incident which has called attention to the effusion, but that it is not primarily responsible for it—in other words, that the case is one of the kind which we are considering. In the absence

of catamenial irregularity or uterine disorder some other reason must, on the other hand, be sought for the local condition.

Treatment.—In the matter of treatment a correct interpretation of these cases is of vital importance, especially in young subjects in whom the chronicity of the condition and the ofttimes delicate aspect of the patient suggest tuberculous disease if the attention be too much concentrated on one knee only, and may lead to a treatment by splints and complete rest which in the catamenial and uterine cases is the very worst for adoption and should be rigorously avoided. The primary treatment should be directed to the correction of the faulty functions, whilst moderate exercise and massage for the knees, combined with the healthiest of outdoor lives, are collateral indications—beyond everything, splints of any kind should be avoided, and on no account should the patient be allowed to lead an invalid's life unless the loss of blood, pain, &c., render this absolutely unavoidable. In the absence of acute symptoms arising from injury the condition of the knees need lead to no restriction in the exercise of an ordinary person.

Prognosis.—The prognosis in these cases, if treated on the lines indicated, is always good, provided that the primary cause of the effusion can be cured, in which case recovery invariably follows unless the condition has persisted so long as to produce permanent changes in the joint. If the primary condition proves intractable the effusion will occur continuously or recurs at intervals. In cases where the effusion is continuous or is constantly recurring an increasing weakness of the knees occurs and in the later stages, when the health becomes broken down by frequent loss of blood or great pain, œdema of the legs sooner or later follows, but in this there is no specific meaning since it is merely the result of continual exhausting illness.

Such, gentlemen, are the main points in connexion with this interesting condition to which I am anxious to direct your thoughts. So far as I know the affection is not one which is commonly recognised, although, of course, it may be well known to some people. Since, however, a well-known obstetric physician assured me some time since in conversation that the subject was new to him I presume that it cannot be altogether familiar to the generality of us. This amongst other reasons must be my excuse for occupying so much time to-day in considering the matter.

Note.—Since the delivery of this lecture the following striking case amongst others has come under observation. A woman, aged 47 years, had up till quite recently been menstruating with exceptional regularity; she had always been in good health and very active in her habits, taking much bicycle and walking exercise. The last two "periods" had been very profuse and were followed by an almost continuous flow which was very obstinate to treatment. A short time before the case came under my notice the nurse in charge of the case called attention to the existence of swelling of both knees. The patient was anæmic and at times lost much blood; both knees were swollen from effusion, the joints being baggy—not distended; there was neither local heat nor tenderness—indeed, beyond a feeling of weakness nothing abnormal was complained of by the patient. The well-marked point in this case was the singular way in which the effusion rose and fell in relation to the occurrence of the uterine hæmorrhage. The greater the loss of blood the greater was the amount of effusion in the knees. Upon the cessation of the hæmorrhage for a few days the effusion would almost disappear only to reappear in the usual quantity with the recurrence of the uterine flow. In this case as usual the effusion was confined to the knees. At the termination of the climacteric the knees recovered spontaneously and have given no sign of trouble since.

TORQUAY HOSPITAL AND PROVIDENT DISPENSARY.—The fifty-seventh annual report of this institution shows that during 1900 the in-patients numbered 389, against 359 in 1899, and that 692 out-patients were treated compared with 518 in the previous year. This is exclusive of 591 patients who were treated in the ophthalmic department. In the provident dispensary 196 new members were admitted and 228 were removed from the books. The financial statement showed that the expenditure amounted to £2246, and the income from all sources was £1938. A special appeal has been made for funds, with the result that £324 have been already received.

Three Lectures
ON
THE SURGERY OF PREGNANCY AND LABOUR COMPLICATED WITH TUMOURS.

Delivered at the Medical Graduates' College and Polyclinic on Jan. 11th, 18th, and 25th, 1901,

BY J. BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE III.[1]

Delivered on Jan. 25th.

PREGNANCY COMPLICATED BY CANCER OF THE NECK OF THE UTERUS; TUMOURS OF THE PELVIS; MISPLACED VISCERA; SEQUESTERED AND QUICK EXTRA-UTERINE FŒTUSES.

GENTLEMEN,—We will begin this lecture with the consideration of what to my mind is the most appalling of all the complications of pregnancy—namely, cancer of the neck of the uterus. One of the most significant clinical features in regard to cancer of the neck of the uterus is the fact that it is almost exclusively confined to women who have borne at least one child. In 100 women with cancer of the cervix which I carefully investigated in regard to this point there was only one exception, and she was married. Even in this case a miscarriage could not with certainty be excluded. Czerwenka has recorded an interesting observation bearing on this subject. A woman, 35 years of age, had a double uterus with cancer of the left cervix. This uterus was removed by panhysterectomy. The vagina was double; coitus was practised in the left half. The left cervix had become cancerous, the corresponding uterine body contained two small fibroids, and the left Fallopian tube had become a pyosalpinx.

It is somewhat difficult to understand how a woman with cancer of the uterus can conceive, but it is quite certain that it happens, and even when the disease is well advanced; further, it is by no means easy in the early stages to detect the complication, because in many cases cancer of the cervix leads to enlargement of the uterus. Dr. Playfair exhibited a uterus at the Obstetrical Society of London in which he had performed vaginal hysterectomy for cancer of its neck, and to his astonishment he found that it contained an embryo of the second month.[2] I feel convinced that in some cases cancer of the neck of the uterus grows more rapidly than some of us realise, and it is not beyond the bounds of reasonable probability that this woman's cervix was healthy at the time she conceived, and the amount of diseased tissue present at the time of operation represented two months' growth. It is consistent with what we know of the growth of cancer in the breast, for in this situation carcinoma increases with extreme rapidity during lactation. Judging from my own observations I think that cancer of the neck of the uterus is not an uncommon complication of pregnancy, but I believe that cases in which uterine cancer offers obstruction to delivery are rare, and this for two reasons: cancer of the neck of the uterus predisposes to abortion, and when it has advanced to such a stage as to occupy the vagina with an obstructive mass the effect of it upon the patient is such as endangers and ofttimes kills the fœtus. Indeed, it may be laid down as a principle that when considering the question of Cæsarean section upon a woman with cancer of the cervix the intending operator should first satisfy himself that the child is alive. The following case not only illustrates this fact but will serve to demonstrate that it is a fortunate circumstance that in many cases in which this dreadful combination of cancer of the cervix and pregnancy exists that there is a great tendency for abortion to occur. A

---

[1] Lectures I. and II. were published in THE LANCET of Feb. 9th (p. 382) and 16th (p. 452), 1901.

[2] Transactions of the Obstetrical Society, vol. xxxvii., p. 198.

poor woman about seven months pregnant was admitted into the Chelsea Hospital for Women with the hope that I would perform Cæsarean section. On examination the extensive nature of the cancer clearly barred any operative measures for its relief, and although there could be no doubt that the uterus was gravid there existed a good deal of doubt about the vitality of the fœtus. I decided to watch the case and await events, and if we obtained clear evidence that the child was viable we could then take steps for deliverance unless miscarriage happened, and there were threatenings of such an event. About five days later abortion occurred and a dead, shrivelled fœtus escaped from the uterus. There was very little bleeding and in due course the uterus settled down and eventually the woman returned to her home and died some month later.

Now and then it will happen that such cases urgently demand surgical treatment and the surgeon will have to exercise his mind as to the best method of dealing with the complication. I was on the horns of this dilemma in 1899 when a woman, 33 years of age, and mother of several children, was transferred from Queen Charlotte's Hospital to the Chelsea Hospital for Women under my care. The poor patient was eight months advanced in pregnancy and had extensive cancer of the neck of the uterus. It surrounded the vaginal portion of the cervix like a ring, but did not invade the vaginal walls or infiltrate the broad ligaments. Although the conditions as to remote results were not too propitious operation was possible and the immediate outlook was not too bad. The case was the subject of a very anxious consultation and there were three courses suggested: (1) induce labour and remove the uterus after the puerperium; (2) amputate the cervix and let labour follow; and (3) abdominal panhysterectomy. I deliberately chose the third course, as it would enable me to rescue a viable child and at the same time remove the cancerous uterus. The operation was carried out in the following way: the patient was etherised and the abdomen was freely incised in the middle line. The broad ligaments were clamped with forceps and cut; the uterine arteries were exposed and clamped and the uterus with its contents was cut away from the cervix and handed to an assistant. Thus whilst I was occupied in securing the vessels an assistant opened the uterus and extracted the child. This is as far as I know the first record of a child being delivered alive from a uterus detached from its mother. Having secured the vessel I then removed the cancerous cervix, having taken the precaution to protect the intestines by sterilised towels. The vaginal edges were sutured and the peritoneum closed over it, and the abdominal incision secured as usual. The patient did not rally well from the operation and paresis of the intestines supervened and she died on the fourth day. The child flourished well during many days in an incubator; then he began to waste and died when about 14 days old.

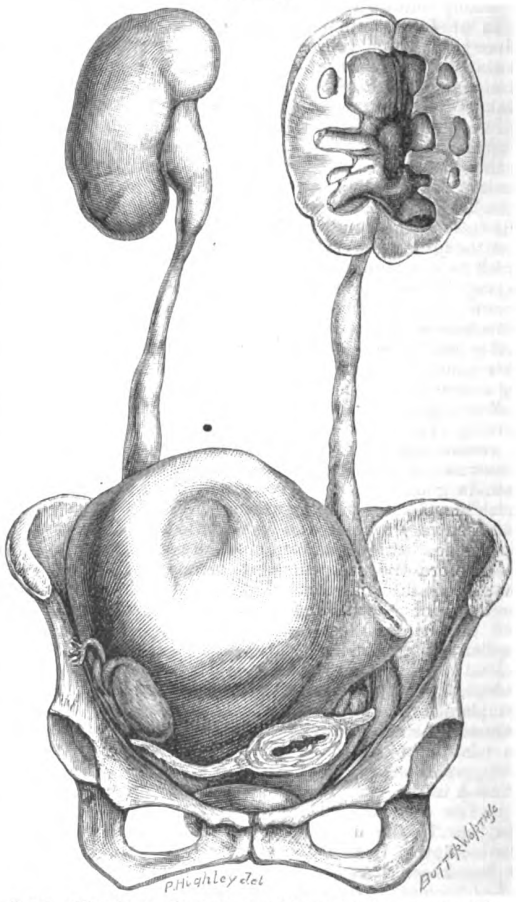
It occasionally happens that even when the child is dead cancer may induce such changes at the neck of the womb as to render surgical interference indispensable. In 1891 a woman, 35 years of age, mother of six children and known to have cancer of the neck of the uterus, was taken in labour. Until the onset of "the pains" no one suspected pregnancy. On examination a hard cancerous infiltration of the cervix was found and the umbilical cord had prolapsed and ceased to pulsate. The woman was admitted into the Middlesex Hospital; 48 hours later Dr. W. Duncan performed Cæsarean section and extracted a dead and putrid child with its placenta. The patient died 41 hours after the operation.[3]

A study of the literature, which, by the way, chiefly consists of isolated records of cases, indicates that the course usually followed when pregnancy, complicated with cancer of the cervix, goes to term is to perform Cæsarean section, especially as the cancer is, as a rule, too extensive to permit radical surgical measures. When the cancerous condition of the cervix is detected before the mid-period of gestation it would be desirable to empty the uterus and perform vaginal hysterectomy if the disease is not so extensive as to preclude the hope of a successful issue. On the other hand, when cancer of the cervix is detected in the late stages of pregnancy the cervix may be removed without disturbing the pregnancy. In one successful case, performed in the seventh month, pregnancy went to term and labour occurred naturally. A year later there was extensive recurrence (Wallace). A study of the records indicate that the best operative results have followed radical operations by the vaginal route.

Cancer of the rectum and pregnancy.—Of this unusual complication and obstruction to delivery I only know of one example. The patient was in the Middlesex Hospital Cancer Wards, under the care of the late Mr. J. W. Hulke in 1894, for cancer of the rectum for which colotomy had been performed. On admission the patient was found to be pregnant, "and when the full time came that she should be delivered" Mr. Hulke transferred the patient to the ward for the diseases special to women, and Dr. Duncan successfully performed Cæsarean section.[4]

Tumours of the pelvic bones.—Among the rare obstructions to labour must be reckoned tumours of the pelvis other than those which arise from the uterus, ovary, or Fallopian tubes. In the text-books of midwifery a chondroma arising from the pelvic bones is nearly always mentioned; it is an extremely rare tumour independent of pregnancy and when it complicates this condition it offers a formidable obstruction to delivery. The remarkable effects which such tumours produce on the pelvic viscera are shown in Figs. 7 and 8, taken from a specimen in the museum of University

FIG. 7.



Pelvis with a large chondroma arising from the sacrum and complicating pregnancy at term. (Museum of University College, London.)

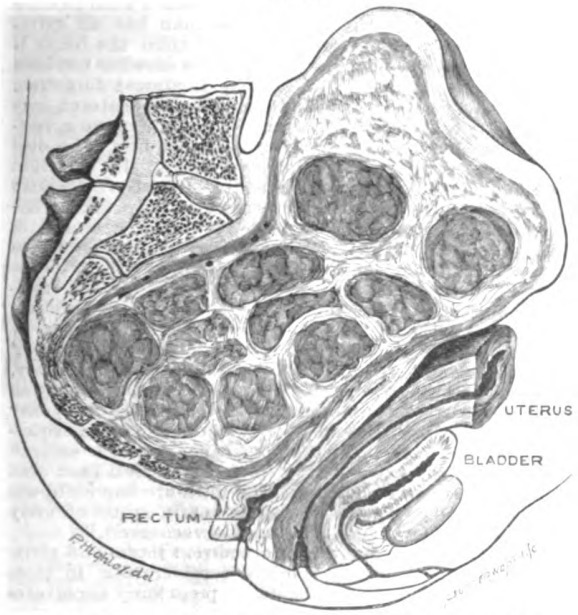
College, London, obtained from a woman, 21 years of age, who was admitted to the hospital in 1893 in labour. The patient came under the care of Dr. Herbert Spencer who performed hysterectomy and saved the life of the child. The mother died on the ninth day after the operation. The parts concerned are shown in sagittal section; it will be seen that the tumour is intimately connected with the third, fourth, and fifth sacral vertebræ and that it has utilised all the available space in the true pelvis and has displaced and compressed the rectum, vagina, and

[3] Middlesex Hospital Reports, 1891, p. 159.

[4] Middlesex Hospital Report, 1893, p. 215.

urethra against the pubes. The ovoid shape of the tumour, and in consequence its elliptical outline, is characteristic of all tumours which mould themselves in the true pelvis—e.g., the pelvic segments of large ovarian cysts and cervical fibroids and the head of the fœtus after a long labour. The most lethal effect of the tumour even more than the obstruction it offered to delivery is the insidious change it produced on the ureters, for both were dilated and the pelvis of each kidney contained pus. A perusal of the clinical post-operative history indicates that she probably died

FIG. 8.



The pelvis in the preceding drawing in sagittal section. The dark patches are spurious cavities due to softening of the cartilage.

in consequence of the great disorganisation of the kidneys. The tumour is a chondroma, part of which has ossified; it has a firm fibrous capsule. The spaces in the tumour are spurious cavities due to myxomatous changes in its tissue. This woman was known to have a tumour in her pelvis seven years previously to her tragic death. The structure of the tumour is consistent with such a history.

A somewhat similar though not so severe a case was placed under my care in the Chelsea Hospital for Women by Dr. W. H. Fenton. The patient, a married woman, 32 years of age, mother of two children and five months pregnant, was found to have a tumour in the pelvis which so narrowed the outlet that delivery by the natural channel would be an impossibility. On careful examination the tumour was thought to be an ovarian dermoid incarcerated in the pelvis and it was decided that an attempt should be made to perform ovariotomy. There were other features in the case which demanded consideration; the urine contained albumin (about one-half) and the uterus was so large as to raise the suspicion of hydramnion. The general aspect of the patient was not good. However, the case demanded surgical intervention and I performed cœliotomy; instead of an ovarian dermoid I found a large, hard, solid tumour growing from the anterior face of the coccyx and lower sacral vertebræ extending almost completely across the pelvis. I had no alternative but to perform hysterectomy, although this was a serious operation in view of the albuminuria. Fortunately, the patient made one of the most rapid recoveries I have ever known after hysterectomy and she left the hospital convalescent in 14 days. She reported herself at the end of three months and an opportunity was taken to examine the urine; the amount of albumin had not altered. We kept in touch with the patient and learned that she died two years after the operation from pneumonia.

Post-rectal dermoids.—In considering pelvic tumours it is well to bear in mind that dermoid tumours may occupy the hollow of the sacrum behind the peritoneum and the rectum and be absolutely independent of the ovaries; this is proved by the fact that they occur in men as well as in women. A case was carefully observed in the Royal Infirmary, Newcastle-on-Tyne. The patient, a woman, 49 years of age, was under the care of Mr. Frederick Page and he removed the tumour through the perineum by means of a transverse incision between the anus and the coccyx. He extracted the pultaceous matter with a spoon and then enucleated the wall of the dermoid. The woman recovered. The contents of the tumour weighed three pounds; its walls were furnished with hair and the tumour resembled a pumpkin in contour and in size. The best-known example of a post-rectal dermoid in a man is recorded by Ord. I collected all the records of post-rectal dermoids I could find and drew attention to them in my book on "Tumours." The latest contribution to this subject is an article by Skutsch,[5] and he gives an account of two cases under his own care in women. One of them is especially interesting in association with the subject of this lecture because the patient, a woman, 28 years of age, was pregnant at the time she came under observation. This woman had had three children previously and a miscarriage. At the time she came under Skutsch's care she was five months pregnant and had difficulty with the bladder and rectum. He succeeded in evacuating the cyst contents through a transverse incision in the perineum. The tumour extended as high as the pelvic brim and he succeeded in extracting a portion of the wall and draining the cavity. The mother recovered from the operation, the pregnancy was not disturbed, and she was delivered at term without difficulty. The cyst wall was carefully investigated microscopically and determined to be dermoid.

Kidney in the hollow of the sacrum.—It is necessary for a tumour to be composed of very substantial tissues to offer an effective bar to delivery, and, as I pointed out in dealing with ovarian tumours incarcerated in the pelvis by a gravid uterus, in the majority of instances those which proved the most formidable were in nearly all instances dermoids. I am cognisant of one case in which a kidney occupied the hollow of the sacrum and did not oppose delivery, and in its turn the passage of the fœtus does not appear to have affected it injuriously. The facts of the case are not without interest. The patient, a woman, aged 33 years, was known to have a painful swelling behind the uterus and of a character which suggested a distended Fallopian tube. Cœliotomy was performed by Dr. Heywood Smith, and when the parts were exposed we found the uterus to be of the unicorn variety and to possess one Fallopian tube and a well-developed ovary on the right side. The left side of the uterus was smooth and rounded and lacked a broad ligament ovary and Fallopian tube and anything representing the left round ligament. Knowing that this malformation of the internal genital organs is usually associated with defective development or misplacement of the kidney, corresponding to the defective half of the uterus, I was allowed to make a careful examination of the renal organs. The right kidney occupied its proper position; the left one lay in the hollow of the sacrum behind the peritoneum and proved to be the body which we had recognised behind the uterus and thought to be an enlarged Fallopian tube or ovary. The abdominal incision was closed and the patient made an uninterrupted recovery. About 14 months afterwards the patient conceived and had the satisfaction of being delivered easily at full term of a fine child.[6]

Many years ago I prepared a specimen of a kidney occupying the hollow of the sacrum and placed it in the museum of the Middlesex Hospital (Fig. 9). The parts were obtained from a man, and at the time I drew attention to the fact that a kidney in such a situation in a woman would constitute a clinical puzzle. It is a remarkable fact that within the space of three months I received for examination and report two kidneys removed from the hollow of the sacrum by the same operator from women. One of these kidneys was hydronephrotic. Thus I have knowledge of four cases in which the kidney was a pelvic organ, three in women and once in a man. In one of the instances it was associated with pregnancy and an unimpeded delivery.

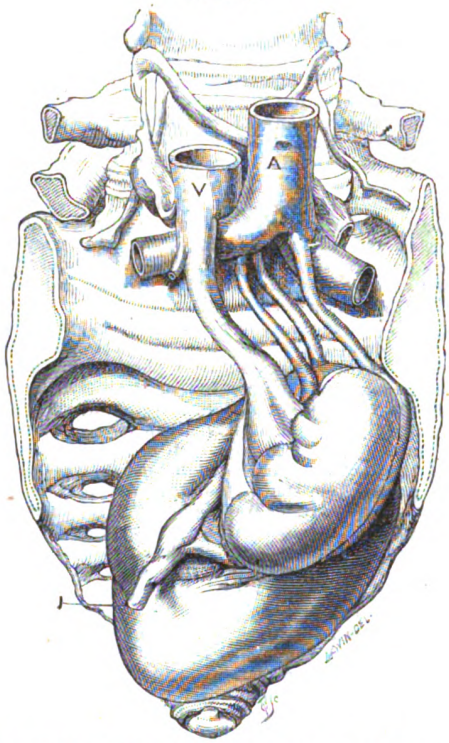
The spleen.—One of the rarest complications of pregnancy among the class we are considering is an enlarged and moveable spleen. In May, 1900, a woman, 34 years of age, mother of seven children and two months pregnant, was

[5] Zeitschrift für Gebürtshulfe und Gynäkologie, Band xl., 353.
[6] THE LANCET, April 16th, 1898, p. 1051.

placed under my care on account of a very mobile, painful, and troublesome swelling in the left iliac fossa, which furnished the physical signs and possessed the shape of a spleen. I performed cœliotomy and the diagnosis proved correct; the spleen was removed and the patient made a quick and uneventful recovery. In December the child was born and the mother reported herself in excellent health notwithstanding that she lacked a spleen. The full details of this case will be found in the Transactions of the Clinical Society of London, vol. xxxiv., p. 26. I have not been able to find another record of splenectomy during pregnancy.

A little reflection on the subject of these lectures makes it clear that tumours which may complicate pregnancy

FIG. 9.



Kidney occupying the hollow of the sacrum. A, Artery. V, Vein. U, Ureter. (Museum of the Middlesex Hospital.)

constitute a formidable list, and there are occasions when it becomes a matter of great difficulty to determine the nature of an obstructing tumour. I remember on one occasion being present at an operation which was undertaken for a suspected tubal pregnancy, but, strange as it may seem, both Fallopian tubes were converted into large sacs of pus and the uterus was gravid. But the enlarged tubes were removed and abortion occurred a few days after the operation. The pregnancy had advanced to the third month. The patient recovered.

A very remarkable case in which the uterus containing several fibroids simulated retroversion of the gravid uterus has been recorded by Cullingworth. Eventually operative interference was undertaken and a fœtus of four and a half months which had developed in the Fallopian tube was found in addition to the fibroids.[7]

In many instances, of course, the determination of the precise nature of the obstructing tumour is not of any serious moment, in others it is all-important, and I am sure that many of us, when face to face with some of these difficult cases, have felt like the Prince of Morocco when, hoping to choose the casket containing "fair Portia's counterfeit," he says:—

"Some god direct my judgment!"

I have thought it desirable, although not strictly in accord with the title of the lectures, to briefly mention a serious, though fortunately a very rare, complication of labour—namely, the presence of a fully-developed extra-uterine fœtus in the pelvis. I am persuaded to do this because on one occasion a solid ovarian tumour incarcerated in the pelvis by a gravid uterus led the physician in charge of the case to regard it as an extra-uterine child; also because a sequestered extra-uterine fœtus constitutes in some conditions a very formidable obstruction to delivery.

Labour complicated with sequestered and with "quick" extra-uterine children.—It is a well-established fact that uterine and tubal pregnancy may run concurrently and both go to term; this may be described as the most dangerous combination to which child-bearing women are liable. The particular form of this combination to which I wish to draw especial attention is that where the woman has an extra-uterine pregnancy which goes to term and then the fœtus is sequestered in the pelvis. The nature of the case has not been recognised and in the course of time is almost forgotten. It is a fact that a woman with a fœtus thus sequestered may subsequently conceive in her uterus. Stonham made a post-mortem examination on a woman, 43 years of age, who died from bronchitis when seven months pregnant. In the right mesometrium he found a sequestered fœtus partly macerated and partly in the soapy condition known as adipocere. The uterus contained a fœtus at about the seventh month of gestation.[8] Leopold has recorded a very remarkable case concerning a woman who had had seven children. After the fourth child she had, according to the evidence, an extra-uterine pregnancy, then three more intra-uterine children, and lived to the age of 70 years; at the necropsy a sequestered fœtus which she had carried 35 years was found.[9] This case, and others which could be quoted if necessary, serves to show that a sequestered fœtus is not necessarily an impassable barrier to the child. To Worrall of Sydney belongs the credit of not only correctly diagnosing a sequestered fœtus as a complication of pregnancy, but he successfully removed the extra-uterine fœtus which had been dead about two years by cœliotomy. The intra-uterine child was born the day following the operation, but in spite of every care it died in a few hours. The mother recovered.[10]

In dealing with the question of concurrent intra- and extra-uterine gestation the cases require consideration in three categories. 1. Cases in which uterine pregnancy supervenes on a quiescent (sequestered) extra-uterine fœtus and goes to full term. In these circumstances it may end happily and, as in Leopold's case, be successfully repeated. 2. An extra-uterine and a uterine pregnancy begin simultaneously, but the complication is recognised in the early months and terminated by surgical intervention (Walther, Hermes, Strauss). 3. Uterine and extra-uterine pregnancy running concurrently to term. All the recorded examples of this extremely rare combination have, with one exception, ended in disaster to the mother.

In order to show what a disastrous conjunction a combined intra- and extra-uterine pregnancy is at term, with two "quick" children, I have drawn up a table of some records easily accessible to English readers which plainly shows how deadly it is for the mothers and it also sets forth the fate of the children. To these cases I have added the year of record and it will be seen with satisfaction how rarely this deadly combination runs to term. There is one bright feature disclosed in the table, and that is the good fortune which fell to Ludwig, for he not only had the satisfaction of saving the life of the mother, but the intra- and extra-uterine children were also successfully rescued—a feat in obstetric surgery of which any man may justly feel proud.

Table showing Cases of Concurrent Intra- and Extra-Uterine Pregnancy running to Term, with the Fate of the Mother and Children.

THE DIAGNOSIS AND TREATMENT OF ABSCESS IN CONNEXION WITH THE VERMIFORM APPENDIX.

BY RUTHERFORD MORISON, F.R.C.S. ENG. & EDIN.,
SURGEON TO THE NEWCASTLE-ON-TYNE ROYAL INFIRMARY.

MUCH controversy still exists as to the treatment, operative or otherwise, of cases of appendicitis, but all authorities agree that the presence of pus makes operation imperative. The diagnosis of abscess in connexion with the appendix becomes in consequence one of signal importance. The ordinary signs of pus-formation are no useful guides: a rigor or pus temperature, redness and œdema in the right iliac fossa, or the presence of deep fluctuation, if found, are one and all suggestive of the presence of pus; but these signs are so exceptionally present that if a diagnosis is to be based on them it will seldom be made. A rigor is rare; as a well-marked and remembered sign it has only occurred in three of my tabulated cases. A pus temperature—that is, a temperature low in the morning and high in the evening, followed by night sweats—is the most constant and important of the signs mentioned and is not often absent. Redness and œdema in the right iliac fossa only occur when pus has made its way through the abdominal wall and the abscess is about to open externally, a rare termination. Fluctuation can occasionally be found in neglected abscesses which have been allowed to attain to a large size. It is a fact, and it is of overwhelming importance to know it, that an abscess may be present and all of these signs may be wanting, and that with a large and dangerous abscess the patient may appear to be convalescent. I have notes of four such cases on which I have operated during the past year. The following will suffice as an example.

CASE 1.—A patient under the care of Dr. A. Campbell, Monkwearmouth, was admitted to the private hospital on July 27th, 1900. Ten days previously he had been suddenly seized with acute abdominal pain and vomiting. Similar attacks had troubled him before. He had to go to bed and was feverish and ill for five days, when the pain became localised in his right iliac fossa. During the past five days his temperature and pulse were normal. He regarded himself as convalescent, and he walked from the cab upstairs to his room. When seen there he was dressed and going about and said that he felt well. On bi-manual examination (one hand on the abdomen and a finger in the rectum), a large tender mass was found on the right side of his pelvis. Operation disclosed an abscess containing about three ounces of foul pus and a perforated appendix hanging over the brim of the pelvis.

The two essentials for diagnosis are: (1) the history; that of a sudden severe attack of abdominal pain gradually becoming localised in the right iliac fossa, attended by vomiting and fever, and followed by an abdominal illness; and (2) the discovery of a definite tender tumour, with usually rigidity of the abdominal muscles, in the neighbourhood of the appendix. The diagnosis of appendicular abscess made on these grounds will less often be wrong than any other in abdominal surgery, and every such case should be operated upon.

In a previous series of papers on Appendicitis, published in the *Edinburgh Medical Journal* for March, April, and May, 1897, I drew attention to the clinical importance of the anatomical position of the appendix, and again wish to point out its diagnostic and prognostic significance. For surgical purposes the anatomical positions of the appendix may be described as: (1) on the inner side of the cæcum and pointing upwards into the area occupied by the small intestine; (2) on the outer side of the cæcum, and pointing to the gutter on the outer side of the ascending colon which leads above into the hepatic pouch; (3) below and internal to the cæcum and pointing into the pelvis; (4) behind the cæcum in the sub-cæcal fossa; and (5) behind the ascending colon and resting upon the peritoneum and fascia, or fascia alone, covering the psoas muscle. An appendix in either of these five situations surrounded by a localised collection of pus produces characteristic physical signs by a careful study of which, in the great majority of cases, the position of the appendix and the relations of the abscess can be, and are in my wards, correctly foretold. Such refinement of diagnosis does not meet with great encouragement at the present day, but considering the difference in prognosis of an abscess on the inner and one on the outer side of the cæcum, and the advantage to the surgeon of knowing where to look for the appendix in a difficult case, complete diagnosis must be regarded as a valuable aid both to prognosis and to treatment.

The commencement in the greater number of cases of appendicular abscess is by a sudden severe pain, often waking the patient from sleep in the early morning. (See paper previously mentioned.) The pain at first cannot be definitely localised, but it is frequently referred to the epigastrium; later, it descends to the right iliac fossa and continues there long enough as a rule to prevent the patient from sleeping for two or three nights, it then gradually subsides, leaving marked tenderness behind. The pain is immediately, or shortly, unless in exceptional instances, followed by vomiting and a febrile illness of such severity as to confine the patient to bed for some days. If due importance is not attached to the early history and the presence of an iliac swelling be overlooked, it is not surprising to learn that typhoid fever has been suspected.

The diagnosis of a case which is so acute as to develop an abscess in 24 hours, and a recognition of the appropriate treatment—immediate removal of the appendix—are both easy. It is especially to the more difficult questions of the diagnosis and treatment of the less acute forms that my present paper is meant to draw attention.

1. The position of appendicular abscess inside of the cæcum is indicated in the diagram (see Fig. 1). The walls of the abscess are usually constituted of coils of small intestine and the roof of omentum. When acute tenderness has subsided, such an abscess may be fairly moveable in all directions, and this mobility may raise difficulties in its diagnosis. A small ovarian cyst with twisted pedicle and fixed by adhesions produces symptoms and signs very similar.

2. With an appendicular abscess on the outer side of the cæcum the swelling will be found to commence in the right iliac fossa above the anterior superior spine. As it enlarges it hugs the iliac crest and extends upwards to the ilio-costal space (see Fig. 2). It is quite fixed, and when large makes a definite palpable lumbar swelling. If the appendix in that position happens to be long it reaches upwards into the hepatic pouch, and when inflamed it frequently ruptures at the tip and causes a swelling there, which is generally mistaken for a liver or kidney tumour (see Fig. 3).

3. If the inflamed appendix hangs over into the pelvis, the resulting abscess may be found as (*a*) a limited swelling fixed to the pelvic brim and most readily discovered by bi-manual examination (the hand on the abdomen and a finger in the rectum); or (*b*) the pus may fill the pelvis in varying degree till the recto-vesical or recto-uterine pouch, distended by pus and roofed over by intestine and omentum, comes to resemble a distended bladder or an ovarian cyst (see Fig. 4).

4. An abscess in the sub-cæcal pouch pushes forward the cæcum, which may be felt gurgling over it, or giving a resonant note on light percussion. This abscess is usually small, occasionally it is a little moveable from side to side, and lies deep in the iliac fossa. It may be confounded with the more chronic and less tender tuberculous or malignant tumour at the ileo-cæcal valve (see Fig. 5)

5. An appendicular abscess behind the ascending colon and lying on the psoas muscle produces a lumbar tumour and flexion of the corresponding thigh (see Fig. 6).

The difficulty of diagnosis in pelvic cases, especially in women, requires special mention. The combination of

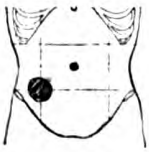
FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

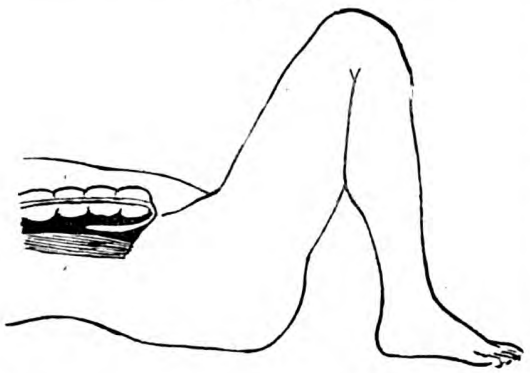
FIG. 5.



ovarian cyst with appendicitis is not rare, and the difficulties of diagnosis are thereby increased. As a typical and not very rare example of this combination I may quote an old case.

CASE 2.—A woman, aged 31 years, a patient under the care of Dr. A. H. Davis, Sunderland, on the evening of April 4th, 1895, felt a pain in the abdomen, but not severe. She took an aperient pill and at 2.30 A.M. was awakened with severe pain. A dose of saline aperient and the application of hot flannels relieved her. In the morning she took a cup of tea, which she vomited. She had hiccough and her bowels were not moved. On the 15th, at 10 A.M., she was seen by Dr. Davis, who found her with a pulse of 80 and a temperature of 100° F., and complaining of general abdominal pain. Her cheeks were flushed, her feet were cold, her knees were drawn up, her mouth was dry, and she was very thirsty. The abdomen was generally tender, but this was most marked in the

FIG. 6.



hypogastrium. An enema given in the evening had no aperient effect, but was followed by intense pain and a feeling of faintness. She vomited once. The temperature was 101·2° and the pulse was 90. There were occasional chills. On the 16th the pain became more definitely referred to the right side of the abdomen, which was swollen, rigid, and tender. On the 17th Dr. Davis found a lump in the right iliac fossa; on the 18th a consultation with Dr. D. Drummond was held, and a pelvic swelling was found in addition to the tumour in the right iliac fossa. I saw the patient first on the 19th (15 days after the illness had commenced). Previously she had always had excellent health, now she was pale and ill-looking; her tongue was red and moist; her pulse was 100, and her temperature was 100°. In the right lumbar region, and extending into the right iliac fossa, a tender, resisting, ill defined swelling was felt. Per vaginam the pelvis was filled with firm exudate fixing the uterus. A temperature chart kept since the beginning of the illness was strongly suggestive of the presence of pus.

Operation was performed on April 20th. The abdomen was opened by an oblique incision in the direction of the external oblique fibres with its centre over the cæcum. The cæcum was found to be glued down over a mass in the right iliac fossa. The pelvic brim was covered by adherent intestines, beneath which a fluctuating swelling was felt filling Douglas's pouch. The intestines above the cæcum were free from adhesion. The abdomen was packed and covered with an antiseptic towel and the patient was placed in the lithotomy position. After vigorous cleansing of the vulva and vagina an incision was made in the posterior vaginal fornix close behind the cervix uteri and about one drachm of purulent fluid escaped. A pair of forceps pushed closed into the opening and drawn out open led to no further result. Between one hand on the abdomen above and a finger in the vagina wound below a cystic swelling could be distinctly felt. The patient was now replaced on her back with an antiseptic towel over the vulva, and the abdominal wound was prolonged backward to the loin and forwards to the middle line, the deep epigastric artery being secured before its division. After separating the adherent intestines the cystic swelling in the pelvis was now seen to be ovarian. It was torn out whole and the oozing bed in which it had been adherent was immediately packed with sponges. The remainder of the abdominal cavity was also packed off with sponges and the separation of the cæcum from the parietes on the outer side undertaken. On tearing through the outer layer of the mesocolon an abscess containing at least two ounces of stinking pus was evacuated. The appendix was searched for by raising the whole of the cæcum from the outer side. It was seen and felt firmly adherent to and flattened on the under surface of the exposed cæcum, where it was left after an attempt to separate it showed that this was unlikely to be accomplished without tearing the intestine. The appendix cavity was sponged dry and carefully packed with iodoform gauze strips, the ends of which were left hanging out from the loin end of the wound. The sponges packing the abdomen and pelvis were next removed and all oozing was found to have ceased. A second cyst was now found in the pelvis and removed. The left ovary and tube were found in their normal position and seemed healthy, though adherent. They were not interfered with. A pair of long clamp forceps were introduced through the abdominal wound down to the opening in the upper part of the vagina, and, guided by Dr. Davis's finger in the vagina, were led outside the vulva, where they were opened and made to seize a thick strand of iodoform gauze, the upper end of which was drawn in so that it just reached into the pelvis, the lower end lying within the vulva. The entire abdominal wound was closed with silk except where the gauze drain and an india-rubber tube were left projecting behind. The first cyst removed was an ovarian dermoid of the size of a cocoa-nut, the second was a parovarian cyst of the size of a turkey's egg. The patient made a good recovery, but 10 months later I had occasion to open a second acute appendicular abscess. Since that time she has remained well.

Further difficulties in pelvic cases are illustrated by the following examples.

CASE 3. *Pelvic appendicitis in a female; pus draining through the Fallopian tube.*—A single woman, aged 27 years, was admitted to the Royal Infirmary, Newcastle, on Sept. 26th, 1899. On the 21st, while in bed, she felt a sudden pain about the stomach and vomited. On the 22nd she took castor oil, which was vomited. An enema administered later brought away some fæcal matter. On the 23rd the pain settled in the right iliac region and she continued to vomit. On the 24th and the 25th she had difficulty in passing urine but her bowels were moved. The pain and vomiting continued. On the 26th she was admitted to the infirmary at 9 A.M. On admission she was flushed, had a coated tongue and a temperature of 100·8° F. and a pulse of 120. The whole abdomen was slightly distended, tender, and rigid. The note over the lower abdomen was dull on light percussion. Per rectum nothing was found. The patient was menstruating and passed through a normal period. After her admission the pain abated, the vomiting ceased, and four days later her temperature became and remained normal. On Oct. 5th, 10 days after her admission, as a pelvic swelling was still palpable from the abdomen, she was examined under an anæsthetic. An indefinite firm mass was felt in the left iliac region. Per vaginam the hymen was found to be intact and the vagina virginal. A soft fluid immoveable swelling, apparently of the size of a fœtal head, bulged into and filled the anterior and lateral vaginal fornices. The bladder was emptied by a catheter and the swelling found to be entirely in front of the uterus. This was confirmed by the uterine probe. On withdrawing the uterine probe some fœtid pus escaped from the cervical canal. The diagnosis suggested was that of suppurating dermoid ovarian cyst ruptured into a Fallopian tube.

Operation was performed on Oct. 10th. The abdomen was opened from the umbilicus to the pubes, when the pelvis was seen to be filled by a mass covered by adherent intestine. The abdominal cavity was packed with sterile gauze and the patient was placed in the Trendelenburg posture. On separating the intestinal coils a large quantity of very offensive pus escaped and was quickly mopped up. The pouch of Douglas was practically a large abscess cavity and the abscess extended upwards into the left iliac fossa. A fæcal concretion was found lying at the bottom of the pelvis, and on drawing the adherent cæcum forward a sloughy opening of the size of a sixpenny piece was found in it at the position occupied by the insertion of the appendix. The whole appendix had sloughed off. The right side of the abscess had been drained by the right Fallopian tube, which was slightly thickened but pervious, and had stinking pus in its lumen. The opening in the cæcum was sutured, the right Fallopian tube was excised, and a large drain opening was made from the bottom of Douglas's pouch into the vagina; the abdominal wound was entirely closed except at the lower end, where a glass tube was left. Cultivations from the gauze drain removed on Oct. 14th, four days after the operation, showed the bacillus coli communis only. On the 18th, eight days after the operation, there was a free discharge of fæcal matter and pus from the vagina, and the temperature rose to 102°. This discharge continued, and on the 24th she was very ill, with a profuse discharge of fæces and pus from the vagina and from the lower part of the abdominal wound, and a temperature of 103° in spite of frequent douching through a tube introduced into the vaginal opening. Constant irrigation was now adopted, and the cavity was flushed through from the vagina to the abdominal wound with sterile hot saline solution day and night. If the irrigator was stopped for a few hours her temperature rose and the irrigator had to be restarted. It was continued until Nov. 9th. She was discharged nearly healed on the 20th. In September, 1900, she returned to have a small ventral hernia, of the size of the drainage-tube, at the lower part of the ventral scar, operated upon. She was in good health, and bimanual examination could discover no sign of adhesions or any other abnormality in the pelvis.

CASE 4. *Pelvic abscesses in a male simulating distended bladder; abscess opened and drained through the abdomen; subsequent rupture into the rectum; sinus persisting.*—A young man, aged 18 years, was admitted to the Royal Infirmary, Newcastle, on May 9th, 1900. He was in good health until 10 days previously, when he was awakened out of sound sleep at 2 A.M. with a severe pain all over his abdomen and vomiting. Since that time he had slept little on account of the pain, had perspired profusely at nights, and had frequently vomited. He had had no urinary trouble. On admission he was slightly jaundiced. His pulse was good (77), and his temperature was 100·2° F.; his tongue was coated with a thick brown fur. The pain came on in paroxysms, making him cry out. His abdomen was enlarged above the pubes by a rounded elastic swelling resembling a distended bladder (see Fig. 4). The bladder was emptied by a catheter, but this made no change in the swelling. Per rectum the pelvic floor was bulged down by a tender swelling which felt like a cyst projecting against the anterior wall and continuous with the suprapubic swelling. Distinct intestinal movements could be felt in the right iliac region.

The abdomen was opened from the umbilicus to the pubes. Some free clear fluid escaped on opening the peritoneum. The intestinal coils in the lower part of the abdomen were congested and matted together with purulent lymph. The cæcum was so covered up by adherent intestine that it was considered to be too dangerous to search for the appendix. The upper portion of abdomen was packed off and the patient was turned over on his side. By separating the adherent intestine above the pubes a large collection of foul pus was tapped and a glass tube was introduced into the cavity and packed round with iodoform gauze. The entire wall of the abscess was formed by adherent intestinal coils. The bladder was protected by adherent small intestine from contact with the pus, hence the absence of bladder symptoms usual in pelvic peritonitis from this or other cause. On May 13th, three days after the operation, he was much better, but still slightly jaundiced. The gauze packing was removed; the discharge from the wound was fæcal. On the 20th his temperature was 102°. He was complaining of abdominal pain and of rectal tenesmus. On the 22nd a distinct soft bulging was felt in the anterior wall of the rectum. The rectal mucous membrane over this was œdematous. He still had tenesmus. On the 23rd it was decided to open the abscess in the recto-vesical pouch through the anterior wall of the rectum and an enema was given. A quantity of pus was passed with this and relief followed. Nothing further was done and he left the infirmary on June 10th in good health, but with a sinus at the lower end of the abdominal wound, which still persists (September).

The importance of bi-manual examination in the male may be illustrated by the following case:—

CASE 5.—A man, aged 41 years, was admitted to a private hospital on June 20th, 1900. He had previously had many slight attacks similar to the present. On June 13th, at 3 A.M., he was awakened by a violent pain, which did not pass off as others had. The following morning he was seen by Dr. McBean, who found his temperature raised. He had vomited, but only slightly. An enema which was administered moved his bowels and gave him considerable relief. He was kept in bed, as the abdomen remained tender in the right iliac region. During the 14th he was a little sick, the pain was less, his bowels were moved, but the temperature continued at 100° to 101° F. On the 15th the question of operation being raised, he was seen in consultation with Mr. W. G. Richardson, who then found him lying in bed comfortably on his back with his legs fully extended. He could move freely in bed; there was no sickness; the tongue was dirty; the temperature was 99° and his pulse was 90. He looked well. In the right iliac region there was a distinctly tender point, but no lump to be felt, and palpation was easy. On the 20th, the day of admission, the patient, a stout, robust man, was not looking so well. The tongue was dirty; the temperature was 100°; there were more local tenderness and rigidity in the right iliac fossa, but no definite swelling. Bi-manually (a finger of the right hand in the rectum and the left hand on the front of the abdomen) a definite tender tumour of the size of a large orange could be felt hanging into the pelvis and fixed to the pelvic brim.

Operation was performed on June 21st. On opening the abdomen the caput cæcum was seen to be adherent low down to the brim of the pelvis with a loop of ileum, which was congested and dilated. The abdominal incision was extended from the back of the ilio-costal space to one inch above the symphysis pubis, the deep epigastric vessels being clamped before their division. The peritoneal and pelvic cavities were then packed off with gauze and an abscess containing gas and stinking pus was easily opened by separating some flimsy adhesions in the angle between the cæcum and ileum. The abscess was cleansed and the appendix was seen hanging over the brim of the pelvis. It was yellow and entirely gangrenous; it only required to be pulled off the cæcum like a slough. The abscess cavity was drained into the loin and packed with iodoform gauze, which was brought out there. The pelvic cavity was drained by a glass tube in the middle line in the inner angle of the wound, in case any infection of the pelvis had occurred before or during the operation. The wound between the drains was entirely closed. Two days after the operation the pelvic tube was removed. On July 18th, a month after the operation, the patient went home with two small granulating sores. Three months later, these surfaces never having been quite healed, he did not feel so well as usual. He was sickly and off his food. When lying in bed he smelt a strong odour and found that warm fluid was trickling down his side. On examination it was discovered that an abscess had opened at the outer angle of the wound, which had been healed for two months, an exit thus being given to about one ounce of pus.

Many patients with appendicular abscess (more than is generally admitted) recover if left alone, and the majority do so by a discharge of the pus into the intestine, the cæcum, or the ileum, close to the ileo-cæcal junction, being the seat of election. The quantity of pus escaping from the abscess may be so large as to be recognisable by anyone when it has been discharged from the bowel, or it may be so small and undergo such changes in its passage as to elude skilled observers. I have on many occasions whilst operating demonstrated the communication between the abscess cavity and the interior of the bowel by passing an instrument into the latter (see Case 6, Case 8, and Case 11).

The discharge of an abscess through the abdominal parietes appears to be usually considered the most ordinary method of spontaneous cure of the abscess, but allowing due deductions to be made for preventive operation it is comparatively rare. Every such case is recognised, but the diagnosis of pus discharging into the bowel can seldom be made on account of the difficulty in its recognition except by operation or by post-mortem examination. I have previously recorded (in the *Edinburgh Medical Journal*) a case in which an appendicular abscess discharged externally and into the bladder with the result that the patient recovered, and in the same paper I report a case in which the abscess discharged into the pleura with a fatal result, though it is possible for a cure to be brought about in such instances by the discharge of pus either through the lung or the chest wall. I have also observed several cases of pelvic abscesses, probably the result of appendicitis, cured by the discharge of pus through the rectum or vagina.

When the tender swelling has been recognised a sudden return of severe pain, followed by collapse, sometimes fatal in a few hours (as in a case recorded in the paper before mentioned), and followed by symptoms and signs of general peritonitis, indicates rupture of the abscess into the general peritoneal cavity. The following case illustrates some of these points.

CASE 6.—A man, aged 23 years, was sent by Dr. P. R. Ingram of Wallsend to a private hospital on March 15th, 1900. When at work on March 3rd he felt pain in his abdomen and went home. Dr. Ingram saw him and sent him to bed. On the following day Dr. Ingram found a definite swelling in his right iliac fossa, and from the symptoms and signs recognised the case as one of severe appendicitis and advised immediate operation. The patient and his friends resented this suggestion and the ordinary methods of medical treatment were adopted. The patient progressed favourably; indeed, he seemed so well as to be convalescent, until March 13th, when reaching out of bed to get something he was suddenly seized with intense abdominal pain. Dr. Ingram saw him shortly after and found him in a condition of collapse, with cold extremities, feeble rapid pulse, and frequent vomiting. On the following day I saw him. He then had all the symptoms and signs of general peritonitis. We discussed the question of operation, but, recognising the grave condition of the patient, the seriousness of an operation in his condition, and the improbability of any good result, we decided to wait and watch for further attempts at localisation of the pus which we felt sure was present. On the following day he was driven carefully in an ambulance bed to the private hospital. On admission his condition was found to be no better than on the previous day. On March 16th, at 2 P.M., the patient appeared to be dying and there were signs of a large quantity of fluid in his abdomen. With just sufficient chloroform to dull his sensibility a short incision was made above the pubes through which a glass drainage-tube was introduced into the pelvis. A large quantity (about a quart) of pus and stinking fluid escaped. He died at 4 P.M.

Post-mortem examination showed general peritonitis. There was a large quantity of pus in the pelvis, with much lymph and matting of the whole intestines. The left side of the abdomen was least involved and there was no fluid there. The hepatic pouch was a large abscess cavity filled with pus and altered blood. The cavity was lined by soft lymph and extended as far down as the brim of the pelvis. On the outer side of the cæcum and the ascending colon there were several (five or six) perforations from a quarter to three-quarters of an inch in diameter, which appeared as if caused by the escape of pus in the bowel. The inside of the cæcum and colon was inflamed and the cæcum contained blood little altered. The inflamed appendix lay along the outer side of the ascending colon with its tip extending into the hepatic pouch. The tip was sloughing and perforated. No enterolith was present.

The abscess, although of appendicular origin, may be in a position remote from the appendix and may show itself at a considerable distance of time after the original attack (Case 5). The following cases will illustrate this point and also prove that general septic peritonitis can be spontaneously recovered from, a fact perhaps not sufficiently recognised.

CASE 7. *Appendicitis and general peritonitis; recovery from general peritonitis; death from peritoneal abscess due to localisation of a general infection.*—A girl, aged 19 years, was admitted to the Royal Infirmary, Newcastle, on August 30th, 1900. She was in her usual good health until 11 days before, when she was suddenly seized with a very severe pain in the right iliac region which made her sweat and vomit. She had had similar attacks previously, but not so severe, and they had always passed off in a few days. On this occasion the pain had got less, but had never left her. She had painful frequent micturition, but no retention, and her bowels acted regularly every day without diarrhœa or tenesmus. Her abdomen swelled and was very tender especially at the lower part. She had gradually got weaker, because, as she said, she had had no sleep at all since her illness commenced and had not been able to take any food. On admission she looked very ill; her face was flushed and slightly cyanotic (suggesting pneumonia), her pulse was 100 and soft, and her temperature was 99·6° F. The upper part of her abdomen moved freely with respiration; below the umbilicus there was no movement and there was a definite swelling like a six months' pregnant uterus. A catheter drew off four ounces of urine but did not affect the swelling. No definite mass or tumour could be felt. The hypogastric tumour and the right flank were dull on light percussion; both were resonant on strong percussion. No bulging could be felt per rectum or per vaginam.

On opening the abdomen the omentum was exposed adhering to the right side of the anterior pelvic peritoneum. Behind it were matted small intestines extending down to Poupart's ligament. An opening was made by separating a coil of small intestine from the brim of the pelvis when foul pus and gas began to escape. This was mopped away steadily as it appeared and took some time to discharge, as 30 or 40 ounces were estimated to be present. When the discharge finally ceased the cavity was freely opened up and packed with gauze. It occupied the whole available pelvis. The appendix was found lying on the outer side of the cæcum and was there adherent. It was gangrenous at its tip which was lying loose. In close relation to it was an enterolith. The appendix was removed and the abdomen was about to be closed when pus was seen oozing from above. A collection was then discovered in the liver pouch. This was mopped up and the pelvis and this cavity were drained by large indiarubber tubes and gauze brought out at the back. The patient was very ill immediately after the operation but rallied completely in four hours. 10 hours after the operation she died.

On post-mortem examination the opening on the right side made at the operation led into the large abscess cavity formed by the pelvis and roofed in by matted small intestine and omentum. Under the right lobe of the liver there was a granulating cavity with a trace of pus in it. The rest of the peritoneal cavity was free from pus, but everywhere there was a little sticky lymph and some recent flimsy adhesions (evidence of recent general peritonitis). The margin of the right lobe of the liver was adherent to the parietal peritoneum, and on tearing through these adhesions a large quantity (fully two pints) of very foul pus similar to that found in the pelvis escaped. This sub-diaphragmatic abscess had pushed the diaphragm to the level of the upper border of the third rib anteriorly and laterally. Below, it was confined to the right lobe of the liver. There was some clear fluid in the left pleural cavity.

CASE 8. *Appendicitis; general peritonitis, which had become localised; abscess; acute septicæmia; death.*—A female, aged 51 years, was admitted to the Royal Infirmary, Newcastle, on Sept. 1st, 1900. She was perfectly well until six weeks before, when her illness commenced suddenly with pain in the right side and vomiting. A bad attack of "inflammation of the bowels" followed this and for some days she was very ill. She gradually improved until two weeks before her admission, when she had another attack of pain. The lump in the side was only noticed two days before. On admission she looked ill and feeble, her temperature was 101° F., her pulse was quick, and her abdomen was distended. In the right loin there was a large swelling like a kidney tumour, which projected anteriorly and extended inwards close to the umbilicus downwards as far as the anterior superior

iliac spine, and upwards as far as the costal margin. On percussion the swelling was dull in the loin and over the greater part of the front.

Operation was performed on Sept. 1st. On opening the abdomen the colon was found to be densely adherent to the parietes. In front of the colon and lying between it and the anterior abdominal wall immediately below the liver a large collection (two pints?) of pus was opened. No prolonged search was made for the appendix. The abscess was drained with a large tube and gauze. On the 2nd, the day following the operation, in the morning she was fairly well; her pulse was 128 and her temperature was 99·6°. About mid-day she became delirious. From this time her temperature gradually rose, the delirium increased, and symptoms of acute septic poisoning developed. She died on the 6th with a temperature of 106°.

At the post-mortem examination the abscess which had been opened lay on the hepatic flexure of the colon and was limited above by the liver. There was no collection of pus in the liver pouch, which was obliterated by dense adhesions. The pelvic cavity was filled with pus and liquid fæces and was shut off from the rest of the abdomen by a roof of matted small intestine. The general peritoneal cavity was obliterated by adhesions, most marked on the right side and diminishing towards the left. The small intestines were universally adherent by long flimsy adhesions, producing an appearance as if the intestines were wrapped up in a network of fine cord with meshes. Both liver and spleen were fixed by firm adhesions. The appendix was lying on the outer side of the cæcum; there was an old perforation within half an inch of its cæcal attachment. On the lower part of the cæcum there was a perforation three quarters of an inch in diameter, which looked as if it was due to ulceration from without into the bowel. There was marked colitis but no ulceration of the colon.

CASE 9. *Appendicular abscess opened and drained; general peritonitis; recovery; death from residual abscess.*—A miner, aged 24 years, was admitted into the Royal Infirmary, Newcastle, for the last time on Dec. 5th, 1899. Seven months before he had been in the Infirmary under Mr. Morison's care for acute appendicular abscess. He was very ill at that time, and it was doubtful whether the peritonitis was still localised or had then become general. On May 25th, 1899, with a minimum of anæsthetic his abdomen was opened on the right side and a large quantity of pus escaped. He was discharged well 23 days afterwards and went to work six weeks later. For six months he felt quite well and did his work, which was heavy (hewer in the pit), regularly, and he was often drunk. Two months before he had been found asleep and drunk on the railway, where he had probably been lying for some hours, and was very cold when discovered. Next day he did not feel well, was sickly, and vomited after taking an aperient. After staying in bed for a fortnight he noticed a small lump of about the size of the end of his finger near the middle of the old scar. This burst and flatus escaped from it. On admission he was much emaciated and anæmic, with a weak pulse and a temperature varying from 99° to 102·6° F. There was a fæcal fistula at the centre of the old incision discharging a quantity of pus and fluid fæcal matter. No mass was to be made out and nothing further was discovered on bi-manual or rectal examination. He continued steadily to lose ground and had a regular morning fall and evening rise of temperature, with profuse night sweats, but no definite indication for operation could be found. On Dec. 17th (12 days after admission) he was suddenly seized with a sharp pain in his right chest and difficulty in breathing. He was much collapsed and looked as though he would die. Next day all the physical signs of consolidation were found and acute lobar pneumonia was the diagnosis made. During the following days his general condition improved and his temperature and other symptoms and signs entirely accorded with the diagnosis. A crisis occurred on the 22nd and the temperature rapidly declined, becoming subnormal on the 25th, when he died unexpectedly.

Post-mortem examination showed that the fæcal fistula led down into the pelvis and its internal orifice was found to open into the ileum about three inches from the ileo-cæcal junction. The appendix was discovered on the inner side of the cæcum, pointing inwards and upwards, and close to it an enterolith was lying free. There were cicatricial changes in the appendix and a perforation was discovered in it when surrounding adhesions had been separated. There was no pus and there were few adhesions in the neighbourhood of the appendix. In the rest of the abdomen the intestines were all matted by old firm adhesions, especially marked in the pelvis; between the adherent coils there were numerous small pockets of pus. The whole of the organs in the upper abdomen were densely adherent. In separating the right lobe of the liver an immense abscess was opened into; it was bounded on the inner side by the liver, on the outer by the chest wall; below, it had gone through the right kidney capsule and destroyed some of its substance (it had not invaded the liver); above, it had gone through the diaphragm by a sloughy opening large enough to admit a finger, and there was fully a quart of pus in the right pleura. The lung was compressed but was not solid as had been supposed.

Treatment.—Operative treatment alone requires consideration. It is dangerous and neglectful to leave pus alone in the peritoneal cavity. In the case of pelvic abscess thought to be due to appendicitis, if the pus can be liberated per rectum in the male and per vaginam in the female this is undoubtedly the safest measure and should consequently be the method of choice. If there be a painful bulging into the anterior wall of the rectum of the male, and there is œdematous mucous membrane over it, and if these are accompanied by rectal tenesmus and passage of mucus, or if in the female the posterior vaginal wall above, in contact with the pouch of Douglas, is distended, this plan is indicated. This operation I have done many times and find that it is both simple and safe. Its one drawback is that the appendix is left and in a considerable percentage of cases causes further trouble. Of this fact the patient should be warned, and told to come back for the removal of the appendix at the earliest period if the pain recurs.

The operation—With the patient under an anæsthetic and in the lithotomy posture the skin surrounding the anus and genitals should be cleansed, shaved, and antiseptic ised. In the case of a male patient the anal sphincter is next dilated and the rectum is cleansed with boric lotion. The upper part of the rectum is then packed with iodoform gauze, which is secured by a pair of forceps or silk. With a Sim's vaginal speculum the posterior wall of the rectum is retracted and the index finger of the left hand of the operator feels for the most bulging œdematous spot on the anterior rectal wall. A metal catheter in the bladder empties it and serves as a useful guide as to the position of the prostate, above which the rectal puncture has to be made. A long strong hypodermic needle is guided by the finger in the rectum up to the spot indicated and is pushed through into the swelling. If pus can now be withdrawn, as is generally the case, a director is forced into the abscess guided by the needle, and the latter is then taken out. A pair of forceps pushed along the director and dragged out open makes a large hole for the pus to escape. The forceps should be dragged out in such a way as to make the opening vertical. If it is made transverse the large vessels running vertically downwards may be torn across and cause serious hæmorrhage. During this time the director should be held in position in the abscess cavity to serve as a guide for a strand of iodoform gauze, one end of which should be left in the abscess and the other outside of the anus. The protecting iodoform plug should then be removed from the rectum and the operation is complete. The after-treatment consists in keeping the external parts clean, dusting with boric powder, and the frequent renewal of an antiseptic pad. In 48 hours the gauze-plug is removed by drawing on the outside end. In females by the same manœuvres the pouch of Douglas is drained through the vagina. The following case illustrates such treatment in a virgin female.

CASE 10.—A girl, aged 19 years, was admitted to the Royal Infirmary, Newcastle, on August 14th, 1899. Five weeks before, at 10.30 A.M., she had a severe attack of cramp-like pain across the lower part of the abdomen which doubled her up and made her feel so ill that she was at once obliged to go to bed. As soon as she got into bed she vomited. She had to stay in bed for three weeks, and her pain was only relieved when she got "pills." She had had no bladder or rectal trouble and her bowels had been regular. She had been treated during the last two years for anæmia and had seldom menstruated. On examination of the abdomen a tender indefinite mass could be felt filling the hypogastrium. Per vaginam the vagina was small and virginal. The posterior fornix was bulged downwards by a tender swelling, filling the pouch of Douglas, and a uterine probe showed the uterus to be lying above and pushed forward by this swelling. The diagnosis arrived at was that of ovarian cyst inflamed and impacted in Douglas's pouch. The abdomen was opened between the umbilicus and pubes and the pelvis was found to be hidden by inflamed adherent intestinal coils. The patient was next placed in the lithotomy posture and a hypodermic needle was guided through the vagina into the swelling behind the uterus. This demonstrated the presence of pus. The vagina and its outlet were enlarged by an incision in the ischio-rectal fossa of the same sort as is made in lateral lithotomy, and a further incision in the posterior fornix allowed of the escape of about a pint of pus. The cavity was packed with iodoform gauze and the abdominal wound was entirely closed. On Oct. 3rd, 1899, she returned to report herself as entirely recovered.

In women the catheter should be passed every six or eight hours till the plug is removed, and as this causes no perceptible irritation it can be left for a longer time than it can be in the rectum where it is apt to give rise to some discomfort. The after-treatment is otherwise similar. No douching is necessary.

In my previous paper in the *Edinburgh Medical Journal*, already referred to, the following sentence occurs: "My position with regard to appendicitis with abscess is this: that in the majority of instances the appendix should be removed at the same time that the abscess is evacuated, and that this can be done without risk and with great advantage to the patient, but that in a minority of cases the operation should be confined to the treatment of the abscess." Since this was written the minority has dwindled, and at the present time I advise the removal of the appendix in nearly every case, feeling that where it has been left the operation is an incomplete one (Case 2). The following case is also a striking example.

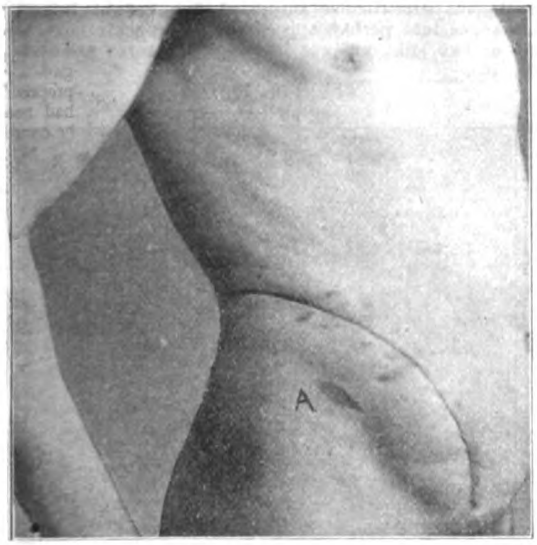
CASE 11.—A man, aged 23 years, was admitted to the Royal Infirmary, Newcastle, on Dec. 23rd, 1899. Three years before the patient had an acute attack of "inflammation of the bowels," followed by abscess. The attack came on suddenly with pain all over the abdomen, becoming localised in a few days in the right iliac region, where a swelling appeared. At the end of five weeks he was very ill and Mr. Morison was called in and operated at once, letting out a large quantity of matter. A tube was left in for three weeks and the wound healed in two months. At the end of three months from the commencement of his attack he went to work feeling quite well. Six months after the operation the patient had another similar attack and a lump formed in the same position as before. After two weeks the swelling got so large that another operation was advised by his medical man. Immediately afterwards he had a copious loose motion containing a

large quantity of yellow matter, and by the next day the swelling was gone and he was able to get up. Since that time he had had four or five attacks at intervals of a few months, never lasting more than a few days and never severe. Three days before admission his last attack commenced and on the second day he observed a swelling. On admission his temperature was 99° F. and his pulse was 99. The scar of the old incision was seen in the right iliac region. His abdomen was rigid and tender on the right side, and in the right iliac region there was a definite swelling. It was immediately above the centre of Poupart's ligament, was resonant on light percussion, and was of limited area. At the operation, after the evacuation of some pus, the perforated appendix was found lying in the sub-cæcal pouch and was densely adherent.

The operation should be done with the object of draining the abscess and removing the appendix and to do this safely undoubtedly requires great care and some practice. It also demands that the patient should not be too seriously ill to tolerate a fairly long operation; that skilled assistance shall be available; and that the surroundings can be so adapted as to approach a hospital standard.

Preliminary treatment.—Except in acute and urgent cases five grains of calomel should be given by the mouth and five hours later a pint enema of salt water. During this time the skin of the right side of the abdomen and back can be prepared as for an ordinary operation, bearing in mind the fact that rough scrubbing may cause diffusion of a localised collection of pus. The patient, surgeon, assistants, nurses, instruments, &c., are prepared with the same care as for any other operation. The incision (for advantages of this see my previous paper in the *Edinburgh Medical Journal*) is made on a line drawn from the back of the right ilio-costal space at its centre to one inch above the symphysis pubis (see Fig. 7). It is commenced in the middle third of this line,

FIG. 7.



and the abdomen is, when possible, opened here for about three inches. In ordinary abscess cases it is then prolonged to the back of the ilio-costal space and in difficult cases anteriorly to the linea alba. In dividing the abdominal wall branches of the circumflex iliac artery will be encountered behind, and in front, close to the edge of the rectus muscle, the deep epigastric vessels are met with; as a rule the incision stops here, but should they require division it is important to expose them by dissection with the knife from the front and to clamp before cutting them, as if the abdominal wall is divided with scissors and the vessels are not seen and secured they retract as soon as cut into the loose sub-peritoneal tissue and are difficult to find. Through the preliminary short incision the peritoneum in ordinary cases is opened and the diagnosis and position of the abscess are verified. When the abscess is adherent to the abdominal wall the muscles overlying it are œdematous, and as the pus is approached the tissues become more infiltrated and dense. Instead of opening the abscess by a continuation of the dissection I prefer at this stage to extend the incision to the back, to open the peritoneum where it is free posteriorly, and to pack off the peritoneal cavity all round the adherent abscess before opening it from the outer side. When the abscess is lying on the outside of the cæcum or ascending colon it is opened by this incision and can be fully exposed from the back and outer side, allowing the appendix to be excised without disturbing surrounding adhesions or opening the general peritoneal cavity. In very acute cases the cellular tissue and muscles of the abdominal wall will be œdematous even though the abscess is not adherent to the parietes. In some cases the cæcum and colon are adherent to the parietal peritoneum and without due care may be injured in dividing the anterior abdominal wall. This is to be avoided by recognising the peritoneum when reached and by pinching it up between the fore-finger and thumb. A non-adherent peritoneum rolled between them feels thin, can be drawn forward, caught by two pairs of hæmostatic forceps and opened. If the bowel is adherent underneath the peritoneum cannot be drawn into a thin fold and must be opened by careful dissection.

In all cases when the abdomen has been opened fully the first step is to pack the peritoneal cavity with long thick strips of sterile gauze wrung out of normal saline solution (see Fig. 8). Need I add that two responsible persons should

FIG. 8.

count these strips independently; that the number should be written down before the operation; that strips must never be cut; and that when the operation is finished the strips of gauze should be again carefully counted? The packing must be done with great care to avoid the separation of adhesions and possible escape of pus, and this is best accomplished by opening the wound and drawing forward the anterior abdominal wall with retractors.

The chief object of this operation is to carry out every step with the parts to be manipulated well exposed to view, and until this can be done satisfactorily the operation wound must be enlarged. By the aid of suitable retractors, and with the incision previously mentioned carried as far forward as the middle line, the most difficult conditions in the lower abdomen or pelvis may be dealt with (see Case 2). When the peritoneal cavity has been fully protected as described the next step is to empty and to cleanse the abscess. This is to be entered from its outer side by pushing the cæcum and ascending colon inwards, and upwards, too, if needful. A steady and slow separation with the fingers allows the pus to escape gradually and it can be mopped up with gauze as soon as it appears (see Fig. 9). If there is a large collection of pus its escape is expedited by turning the patient over towards the right side and enlarging the opening. As soon as the pus ceases to flow from the cavity the abscess is more fully exposed by the separation of adhesions. Its cavity is wiped out with gauze and the appendix is searched for. It may be seen at once or may be most difficult to discover even after a prolonged search. Occasionally it may be felt when it cannot be recognised, its appearance being much altered by the conditions present. The superior longitudinal band of the cæcum leads to its base, but this cannot always be followed. A stercorolith in the cavity of the abscess is usually lying close to a perforation in the appendix and may guide to it. A rounded thick body felt between the finger and thumb may turn out to be the appendix.

With due care it can very rarely remain undiscovered. Then the abscess cavity is to be packed with clean gauze and the appendix is excised. The method of accomplishing this varies with the conditions found. The appendix may

FIG. 9.

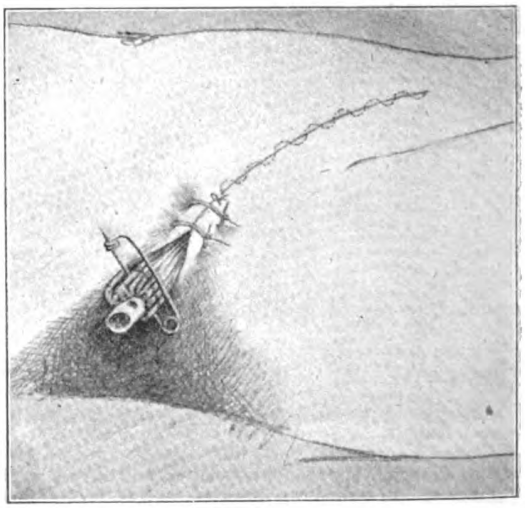
be thickened and densely adherent to the surrounding tissues throughout or entirely gangrenous and lying almost loose in the centre of the abscess confined by the flimsiest adhesions In the case of the former its removal is attended by difficulty and danger; in the latter it is easy and safe. Ordinary adhesions are most readily separated by tearing with dissecting forceps, always bearing in mind the risk of an injury to the adherent bowel and that damage to the appendix need not be feared as it is about to be removed. As a rule the abrupt closed end of the appendix will be a suitable place to commence separation, but occasionally it is easier to divide the appendix between two clamp forceps at its cæcal attachment and leave its extremity to the last. In cases with dense adhesions (as in Case 2) I have since then divided the peritoneal coat of the appendix and without further difficulty or risk have shelled out the whole of its inner coats, thus obviating further appendicular trouble. When the appendix has been separated its mesentery must be divided and the vessels secured either after or before division, setting it free up to the cæcal attachment. When the whole appendix and its mesentery are involved in the abscess the mesentery and vessels may be so sodden and so friable that no ligatures will hold. Gauze packing is then to be relied upon for the arrest of bleeding. A strong ligature is tied tightly round the base of the appendix, which is firmly held between a finger and thumb above to prevent the escape of its contents, and it is cut through, leaving about one-eighth of an inch beyond the ligature. The mucous membrane of the stump is next rubbed with pure carbolic acid and dried and if the wall of the cæcum surrounding it is not inflamed and friable the stump can be pressed into the cæcum where it is retained by a purse-string suture as in ordinary non-suppurating cases. When the cæcal wall is thickened from inflammation sutures as a rule will not hold and gauze packing and free drainage must provide for leakage. Ligatures and sutures for this purpose should be of catgut and digestible, as it is impossible to avoid infection of them. The temporary gauze packing is now removed from the abscess cavity and replaced by an indiarubber drainage-tube, the inner end of which lies in the abscess, the outer in the back of the wound, and by a gauze packing (iodoform or gauze wrung out of corrosive solution and sprinkled with boric powder), so arranged as to check all oozing from the cavity, to depress the stump of the appendix, and to protect the general peritoneal cavity. At the same time it is well to remember that the gauze has to come out before the tube, and the ease with which this is effected is in proportion to the care and method bestowed upon its introduction. When this is all accomplished there is a general washing up of the patient, and fresh towels are placed over the soiled ones. The peritoneal gauzes are now removed, with the exception of the piece last introduced. All are counted, and the suturing of the wound is taken in hand. To this I attach very great importance, for unless it is properly carried out a hernia of the scar may be expected. If it is done in the manner about to be described this is most unlikely to occur. I cannot in this connexion give any exact figures, but what I know sufficiently justifies, I think, an even stronger statement than that which I have made. Of considerably over 100 patients on whom I have operated for abscess of the appendix six have returned to consult me concerning a hernia. Three of these had small scars in the linea semilunaris and one in the linea alba, from which abscesses had been drained. None of them, with the exception of the last (Case 3), had had the appendix excised. The two remaining cases were operated upon by the method I have described, and both had an inguinal hernia on the same side as the scar which I scarcely doubt was a result of the diminished elasticity of the abdominal wall on that side. None that I have seen (and many of them have come for examination) or heard of have any hernia of the scar.

The whole wound is closed except for one inch behind, unless in exceptional instances (Case 5). The first row of sutures (all are of catgut) includes the peritoneum transversalis fascia and transversalis and internal oblique muscles, and is interrupted. When this row is completed a paste made of iodoform powder and corrosive lotion (1 in 1000) is rubbed into the wound, which is cleared of all excess by thorough mopping with sterile gauze. The next layer of sutures, also interrupted, brings together the divided edges of the external oblique. A third row of interrupted sutures tacks the subcutaneous fat and deep layers of the skin to the external oblique muscle; and a fourth buried continuous subcuticular suture of fine catgut brings the skin edges into perfect apposition, except posteriorly, where one or two silkworm gut interrupted sutures are used (see Fig. 10).

FIG. 10.



After-treatment.—The dressing should be renewed frequently until free discharge has ceased. Every two hours is my rule for the first 12 hours after operation. In doing this it is unnecessary to disturb the gauze on the anterior part of the wound if it has been kept separate from the portion surrounding the drains behind. As soon as the serous oozing has ceased dressings should be less often disturbed unless a fæcal fistula develops, when a return to more frequent dressing is needful. On the evening of the operation day, if the patient be an adult, one-third of a grain of morphia is given hypodermically as in all of my abdominal cases. Until flatus has been voided—and this is aided by the passage of a tube into the rectum and by the administration of calomel (one grain hourly up to eight grains), and failing these by the administration of a turpentine enema (one ounce of turpentine and one pint of soapy water) on the second day—no nutriment is allowed by the mouth, nothing but sips of hot water being given. In a feeble patient nutrient enemata (two

ounces of milk, two ounces of beef-tea, and half an ounce of whisky) are administered during this time. On the third day a movement of the bowels is secured by the administration of an enema (one pint of salt water). On the fourth day the gauze drain is removed and care must be taken in doing this not to pull out or disturb the tube, through which a long strong probe may be inserted to prevent kinking whilst the outer end of it is steadied and held in place. On the sixth day, if the discharge is quite small in quantity, the tube can be withdrawn for half its length and cut off. In another few days, depending upon the amount of discharge, it may be altogether dispensed with.

A fæcal discharge from the wound is usually preceded by a rise in temperature. Neither require any special treatment unless in exceptional instances (Case 3), and the wound heals steadily if kept clean by frequently changed dressings. If the appendicular abscess has occupied a position in the abdomen internal to the cæcum drainage should be aided by tilting the patient over towards the right side. This is readily and comfortably done by placing a pillow lengthwise under the left side of the back when the patient is moved off the operating table into bed. No abdominal belt is needed after the wound has healed.

The mortality of this operation is small, and I cannot recall a single instance in which death could be attributed to it. At the present time and for this part of the country I would give the mortality of appendicular abscess at 8 per cent. of operation cases. This will diminish in the same remarkable way as that for strangulated hernia has done so soon as practitioners become more skilled at early diagnosis and realise more fully the need for operative treatment.

CONCLUSIONS.

The early diagnosis of abscess in connexion with the vermiform appendix is of great importance.

A dangerous abscess may be present without any of the ordinary symptoms or signs of pus formation.

The diagnosis is based upon the history of an acute attack of appendicitis and the presence of a definite tender lump.

The position of the appendix and the relations of the abscess may be foretold by a careful study of the tumour.

The diagnosis of pelvic cases in women is attended by special difficulties. In men and women bimanual examination may clear up an otherwise doubtful case.

Spontaneous relief and possible cure may follow the discharge of pus into adjacent bowel.

An abscess, though of appendicular origin, may be remote from the appendix and may be residual. Many of such pus collections are due to the localisation of a general peritoneal infection which has been recovered from.

Early operation is the proper treatment and with few exceptions the vermiform appendix should be removed at the same time as the abscess is drained (pelvic cases form the chief exception to this rule).

The abdominal opening should be large enough to permit of perfect inspection of all manipulation and the abscess should be drained from behind.

To Mr. G. G. Turner, surgical registrar to the Royal Infirmary, Newcastle, I am indebted for an appended list of all cases operated upon by me at the infirmary and private hospital in which pus was found in connexion with the vermiform appendix during the past consecutive working 12 months. I am also indebted to him for the notes of the cases related. Mr. W. G. Richardson, assistant surgeon to the Royal Infirmary, Newcastle, has kindly supplied me with drawings made by himself to illustrate the positions of the varieties of appendicular abscess and the different steps of the operation described.

Newcastle-on-Tyne.

POINTS IN THE CLASSIFICATION AND DIAGNOSIS OF SOME JOINT AFFECTIONS.

BY GILBERT A. BANNATYNE, M.D. GLASG., M.R.C.P. EDIN.,
HONORARY PHYSICIAN TO THE ROYAL MINERAL WATER AND ROYAL UNITED HOSPITALS, BATH.

DURING the course of a year in Bath, as in most other balneological resorts, one is brought face to face with many difficult problems in respect to the classification and diagnosis of joint affections. And this is comprehensible when one considers how little is really known as to the etiology and pathology of most of them. I am writing this paper with the idea of drawing attention to certain points which have struck me as of importance and value, and as being of interest to others working in the same branch of medicine and also with the hope that by the exchange of views we may be enabled to come to some common understanding on various vexed points. For the present no two men seem to agree as to the diagnosis in certain classes of disease; for example, and to show how chaotic our ideas are, take that most common generic name "rheumatic gout." To judge from the number of patients labeled as suffering from that disease one would think it was the most common of all joint affections; yet what is the nature of "rheumatic gout"? Is it gout or rheumatism, rheumatism in a gouty subject, gout in a rheumatic, a disease *per se*, or rheumatoid arthritis? Such are a few of the questions which arise on seeing a case so labeled. On investigation such cases almost invariably can be placed in some more definite and scientific category than that of "rheumatic gout," whose one virtue seems to be that it covers a multitude of sins and errors in diagnosis, but whose entity as a separate disease is doubtful. This looseness in diagnosis in all joint affections arises not so much from want of knowledge or care on the part of those making the diagnosis as from the confusion of ideas which exists, more or less, in all our minds as to certain forms of disease. On reference to most text-books one is struck by the unanimity with which joint diseases are described as they have been described for years, irrespectively of the advance of science, and the absence of method in classing them according to their mode of origin. Now it seems to me that most arthropathies can be referred to several great classes: (1) the bacterial or toxic arthropathies; (2) the nerve arthropathies; and (3) the senile degenerative arthropathies. But besides placing all arthritic cases in these classes it is also possible further to

differentiate between the essential arthropathies—i.e., those in which the joint troubles form the principal symptom of the disease, and the accidental arthropathies—i.e., those which occur with a certain amount of regularity but are not essential symptoms of the disease in which they arise. Thus I should class as essential arthropathies rheumatism, rheumatoid arthritis, gout, senile arthritis, and pulmonary osteo-arthropathy, whereas gonorrhœal, scarlatinal, malarial, and nerve arthropathies are accidental but integral symptoms of some specific condition. I should also explain that by the expression "toxic" I do not wish to confine the meaning of the word to the products of bacterial activity only, but desire to include all products, whether elaborated by specific bacteria or arising from the tissues themselves or by chemical processes. Thus, I am enabled to place gout in a class with other diseases presenting many similar points of interest.

In studying joint diseases one sees how opinion has altered with regard to their origin. A few years ago the nervous origin of most of them was firmly believed in, yet now they can, to a great extent, be marshalled into the bacterial or toxic category. Whilst admitting that pure nerve arthropathies exist, yet from what we know of bacterial activity it certainly seems more reasonable to suppose that they or their products are the cause of most joint changes, rather than that some obscure nerve degeneration or reflex action should be so. As the specific cause in more and more diseases is found to be bacteria or their products, so does it become more likely that such micro-organisms are the cause of nearly all of them.

According to our present knowledge the more common arthritic troubles may be classed as follows:—1. Bacterial or toxic arthropathies: (*a*) bacterial—rheumatism, rheumatoid arthritis, gonorrhœal and scarlatinal arthritis (and probably malarial arthritis); and (*b*) toxic—gout and pulmonary osteo-arthropathy. 2. Nerve degenerative arthropathies, such as occur in tabes, ataxic paraplegia, &c. 3. Senile degenerative arthropathies, such as senile arthritis or malum coxæ senilis. Malarial arthritis may be classed provisionally as bacterial, for I take it that the malarial parasite may be regarded in its action as to all intents and purposes a bacterium, although differing considerably in its life-history.

Another point to notice is that the joint changes in any of the above complaints are not complications, but are all true manifestations of their separate disorders. They are not secondary or separate infections or diseases, but some doubt may still exist whether in a disease having a bacterial causation the bacteria themselves or their products are the cause of the symptoms. Some observers hold that it is the products which give rise to them, whilst others maintain that it is the micro-organisms themselves, and with these latter I side myself. What evidence we have is in favour of this view; for have not the micro-organisms of rheumatism, rheumatoid arthritis, and gonorrhœa been found in the joint structures and joint fluids? In diseases having constant and well-marked changes it is perhaps only natural to expect that the materies morbi itself should be found at the seat of greatest mischief. And if the changes were only caused by products elaborated elsewhere surely they would be much more amenable to treatment, more evanescent in their course, and more unstable in their character. And what better nidus could be found for any micro-organic growth than a joint, surrounded by a fluid medium richly-endowed with nutriment suitable to their growth? No, I cannot but feel that most forms of arthritis, whether the primary and principal manifestation of a disease or secondary and unimportant, must have bacteria as their provocative agent. So far science, in some conditions, has not found the bacterial agent, but all the same the infective character of most of them is manifest, and so, until more perfect and fuller knowledge is ours, one must rest content.

In considering various points of interest in the various diseases I have attempted to classify, one's attention is first turned to rheumatism. It is a big field and a big question for observation, but is much simplified if we consider all its forms and modifications as only so many different manifestations of one and the same poison. If this is not done, and if we look on them as due to secondary or separate infections—a condition of things of which there is no proof—a very large question for speculation is opened out. So far all positive proof lies on the side of one poison capable of affecting many and various structures, and from this standpoint I wish to study certain points.

The first point I wish to direct attention to is the occurrence of swellings or nodules in various structures—of these there are four separate kinds which come under notice with considerable frequency. The first of these is seen in muscular rheumatism, a disease which at one time was regarded as possibly a separate disorder, but which now, I think, is generally acknowledged to be only one of the manifestations of the rheumatic poison. In this form of rheumatism, especially in those who have had repeated attacks, one's attention is frequently attracted to masses or indurated patches in certain muscles pointing to an inflammatory infiltration of the muscle substance. These patches in themselves give no pain and the patients themselves are usually unaware of their presence. The masses are the result of an interstitial myositis, probably brought on by toxic action—at least, that is the idea of those who have studied the question (Leube and Adler).[1] Patients who present these changes not infrequently develop later arthritic changes and endocarditis. These patches are distinct from the subcutaneous nodules so often noted in rheumatism, rheumatoid arthritis, gout, &c., and which appear to be entirely formed of fibrous structure, thus differing from those already mentioned. These subcutaneous nodules have been looked on as being of important diagnostic value, as it was at one time thought that they only occurred in rheumatism and that therefore all cases in which they were seen were cases of that disease. But they have been observed fairly often in rheumatoid arthritis and they occur less frequently in gout, syphilis, influenza, &c. Dr. Hawthorne,[2] whose able paper on this subject has done much to bring the question prominently before the profession, contends that the mere presence of such tumours is no proof of rheumatism. With this I fully agree, for numerous instances of subcutaneous nodules have come under my observation in gout and rheumatoid arthritis and once in gonorrhœal arthritis. They also occur in Maltese fever, a disease which often presents arthritic changes. As one would expect from the nature of the disease, those seen in rheumatism are more transient in nature and smaller than those seen in rheumatoid arthritis. In this latter complaint they are most often seen in the chronic and later stages.

While on this subject there are yet two other forms of swellings in connexion with arthritis which well repay study. One of these is due to the swelling of bursæ in connexion with joint affections and is most frequently seen in chronic gout or chronic rheumatoid cases, and occasionally in rheumatism. Many of these swellings are merely enlargements of normal bursæ and having an intimate connexion with a joint, whilst others have apparently no connexion whatever with one and may even be situated at some distance from any joint. Both kinds are liable to chronic inflammatory changes and may even contain foreign bodies of a cartilaginous nature. They seldom suppurate—never in rheumatoid arthritis—and only as the result of secondary pyogenic infection. I remember one marked case occurring in rheumatism, the patient being a woman, and who, subsequently to her second attack of acute rheumatism, developed an enlarged bursa over the left olecranon. The bursa enlarged rapidly, causing considerable pain, but on treatment subsided almost as rapidly. Some months later she had another attack of rheumatism, less acute than the other, during which she had a similar enlargement on the other side, and which also subsided rapidly. The other and last class of nodular enlargement to which I wish to draw attention is that described by Heberden This form has often been considered to be merely a form of rheumatoid arthritis and to be only seen in that disorder. But, common as it may be in chronic rheumatoid arthritis, I have seen nearly as many in chronic gout. Of this I am certain—these nodes are osseous in character and arise principally from the ends of the phalangeal bones. They are permanent in nature, although sometimes an apparent diminution may be noted under treatment owing to the superimposed tissues being reduced in size.

It is of interest to consider the development and diagnostic value of these nodular enlargements, but with regard to the latter I fear it is small, and this is obvious when we consider that they must all originate through some irritation of the different structures involved. This irritation may be due to micro-organic activity or it may be due to some toxic action, but the result is the same—namely, a chronic interstitial

[1] Medical Record, 1900, lvii., p. 529.
[2] Rheumatism, Rheumatoid Arthritis, and Subcutaneous Nodules, p. 26.

change, resulting in one case in bony nodes, in another in bursal enlargements, in another in fibrous nodules, and in yet another in muscular masses. The explanation of these manifestations is therefore simple. Dr. F. J. Poynton and Dr. A. Paine having isolated their diplococcus in rheumatic nodules strengthens my chain of argument.

As aids to diagnosis I should say muscular swellings are most often due to rheumatism, small subcutaneous nodules also to rheumatism, larger ones to rheumatoid arthritis, bursal enlargements to chronic gout, rheumatoid arthritis, or rheumatism, and bony nodes to chronic gout or chronic rheumatoid arthritis.

Rheumatism has long been looked upon as an infective disease, but many and various have been the micro-organisms found. The researches of Dr. Poynton and Dr. Paine[3] go far to settle the question, but they are not conclusive, for it is too early to say whether the organism isolated by them is the only cause of rheumatism or whether it is only one of several which may give rise to rheumatic symptoms; and while we are still much in the dark as to mixed infections and what influence one micro-organism has upon another in determining its virulence and mode of growth, from the nature of the symptoms seen in rheumatism I feel sure only one organism is the cause. It seems evident that if a certain one is a constant feature in a certain disease or group of symptoms it must have some important bearing in its causation. A fact of importance from my present point of view is that Dr. Poynton and Dr. Paine have been able to demonstrate the presence of their diplococcus in the joint fluids and structures as well as in other sites and by inoculation have been able to reproduce the disease in animals. The inoculations gave rise to arthritis, bursitis, and teno-synovitis, as well as other symptoms, and from each of these inflammations they were able to isolate again the same diplococcus. The chain of evidence seems to me complete, but whether their organism will prove to be the only cause in all cases of pure rheumatism future scientific investigation alone will show. I cannot think that a disease with such well-marked and constant symptoms can be caused by more than one species of bacterium, although this one must have varying degrees of virulence, and its action must be governed by the attacked individual's power of resistance—the different sets of symptoms arising through the fact that the structures affected are influenced by those peculiar forces "natural selection" and "susceptibility of parts." What those forces are is not known, but it is a well-recognised fact that the various tissues of the body respond in different ways to different causes of disease, and that the same cause will affect different structures at different times under apparently similar circumstances, and even in the same person, in different ways.

On the subject of rheumatoid arthritis I feel strongly. One of the principal points in this disease which strikes an observer is that apparently under this name we have two conditions, one acute and the other chronic. The acute form of the disease is seen principally amongst children and in the comparatively young. It is not a common disease of later middle life or of old age. It is more common in females than in males and is the sequela, as a rule, of some other infective disorder, such as influenza, rheumatism, or tonsillitis. It is accompanied by a rise in temperature and swelling of the joints, which become tense from synovial distension or else soft and doughy, but with no cartilaginous or bony outgrowth; in fact, the joint presents an almost pathognomonic soft spindle-shaped enlargement. The extremities are cold and sweating and present a livid mottling, while numerous small freckles or patches of pigment appear on the skin and there may also be other vaso-motor or trophic changes. There may be great pain or almost none. Muscular atrophy is always present and shows marked selection in the muscles or group of muscles affected. Glands proximal to the affected joints are often enlarged, whilst anæmia may be a marked feature. Patients show a loss of fat and vital energy and usually present a peculiar facies which once seen is seldom forgotten. On the other hand, in the chronic cases, which may be chronic from the first or else which may be the later stages of an acute attack, the joints show a progressive crippling which becomes more and more marked as the disease advances. It is most frequent in middle life and in females, is accompanied by no fever, and the general health suffers little; it may affect only a few joints but more often many; it is very chronic in its course but is progressive with exacerbations. If chronic from the outset it usually begins in one small joint as a slight enlargement, which in time increases in size, and the disease then spreads to other joints until it may become difficult to move any joint, from stiffness, pain, and deformity. It is accompanied by much crepitation, usually of the coarser variety, and cartilaginous and even bony outgrowths appear round the margin of the joints as well as in the tendons, bursæ, &c. The movements of the limb may be much interfered with by adhesions, bands, and thickenings, whilst, in very advanced cases, even dislocations may occur. As a sequela of an acute attack, as the acute symptoms subside, the joints become more irregular, more crippled, and in fact come to present all the characteristics just described. It is not within the province of this paper to consider the pathological changes in the joints, but I would mention that the main points are, in the acute form, an inflammatory condition marked by ulceration and destruction of the joint tissues with no outgrowth or lippings, whilst the chronic form is characterised by hardening and thickening and with cartilaginous and osteophytic outgrowth and lippings.

I have so often insisted on the bacterial origin of the disease that I will not do so further here, beyond mentioning that it may be of interest to some to know that some little time ago Von Dungorn and Schneider[4] succeeded in isolating a small micro-organism which, on injection, reproduced the disease in animals. Their micro-organism was found in the joints and gall-bladder. I have not had an opportunity of comparing it with the micro-organism found by Dr. A. S. Wohlmann and myself, but it helps to prove that the disease is due to bacterial infection. Further scientific research will show whether it is due, as I believe, to one specific bacterium and that one the one found by Dr. Wohlmann and myself[5] or to other and mixed infections. As in the case of rheumatism we must wait for further proof.

The other point with regard to rheumatoid arthritis that I wish to touch on is the muscular atrophy so often seen. There are seemingly two varieties, one, exhibiting a selective affinity in its distribution for certain muscles or group of muscles, is seen in the acute forms; the other, as seen in chronic cases, being apparently merely due to disuse. In the acute form the atrophy is so acute and occurs so soon after the onset of the disease and whilst the joint changes, may be, are extremely slight and is so selective in character (the extensors and interossei being principally, but not exclusively, affected) as to preclude the possibility that it is the result of disuse only. It may affect one muscle only or a whole set, but it affects the whole muscle and not a part of it only. It often affects muscles proximal to the joint disease and the tendon reflexes are in most cases exaggerated. In the chronic cases the atrophy affects only those muscles not employed and in direct ratio to the amount of disuse and there is no increase in the tendon reflexes. It has been argued that the form seen in the acute cases, especially by reason of the exaggerated reflexes, lends conclusive support to the dystrophic theory of the origin of rheumatoid disease. But this does not follow, for we know other arthritic lesions may produce muscular wasting having similar characters. All it proves is that this particular form has all the characters of an atrophy due to nerve (probably spinal) irritation. Some hold that this irritation is set up by reflex action, but to my mind it is more probable that it is the result of toxic poisoning. We have no proof that bacteria themselves act on the central nervous system, but the whole nervous system seems to be peculiarly liable to the action of their poisons. For example, take the case of diphtheria or tetanus; or, again, certain toxins are known to act on the vaso-motor system and also on the trophic nerve condition of various structures. Thus tachycardia has been caused, according to Bezançon, by toxins. Bouchard obtained from tuberculin a substance causing dilatation of the blood-vessels, whilst Charrin and Gley obtained toxins with similar properties from the bacillus pyocyaneus, as also did Arloing from the staphylococcus aureus. Vierordt has reported a case of phthisis with neuritis of the vagus, and Semmola mentions the action of the influenza toxins on the vaso-motor centre. In no case of rheumatoid joint disease do the nerve troubles precede the joint manifestations; therefore they must in all probability arise secondarily

[3] THE LANCET, Sept. 22nd (p. 861) and 29th (p. 932), 1900.

[4] Münchener Medicinische Wochenschrift, 1898, Band xlv., p. 1369.

[5] THE LANCET, April 25th, 1896, p. 1120.

to them. But it has been argued that if muscular atrophy can, or does, arise through reflex impulses, so also may some peripheral irritation, say, from such an organ as the uterus, cause impulses capable of originating not only the muscular atrophy but also the joint lesions. This I cannot agree with. I do not deny that it is possible for reflex impulses to alter the nutrition of certain muscles and thus atrophy, but that they can give rise to grave organic changes of an acute and severe character seems to me impossible without at the same time producing some alterations in the nervous centres or in the nerves themselves easily recognisable on microscopic examination. Such changes have not been found, and until they are I cannot believe that reflex irritation alone can cause joint changes of the character seen in rheumatoid disease. In this disease, unless distinct nerve lesions are proved to exist, the theory of infection seems the more probable, the more easily understood, and the more true to clinical experience.

Gonorrhœal arthritis presents several points of interest from a diagnostic standpoint. The arthritis is always secondary to a gonorrhœal attack elsewhere, but it does not always imply that the primary attack is in the urethra. A considerable number of cases have followed infection of the conjunctiva, and this is peculiarly noticeable in children. The joint troubles are caused by the presence of the gonococcus in the joints, and it can be isolated and cultivated from the joint fluids. It is only found, however, with certainty in the early stages of the arthritis. The time of onset of the joint changes may vary: sometimes they occur within a week of the infection, but more often not until after three or four weeks. Cases have even been known to occur many months after the primary infection and when only a slight gleet has existed at the original seat of inoculation. The severity of the joint troubles, therefore, has no relationship to the severity of the primary trouble. It is most liable to affect the larger joints, especially the knees and the joints of the lower limbs rather than those of the upper. For the severity of the symptoms there is an indication in the great effusion of fluid, but the skin is seldom reddened. The pain experienced is not so severe as in a similar condition due to rheumatism. Cardiac disease is rare but not unknown. I remember well a case which in many respects resembled one of ulcerative endocarditis, and the nature of the disease was not cleared up until the occurrence of arthritis in both knee-joints many weeks after the patient was brought under observation. This case was also rather peculiar in the fact that the gleet was of the very slightest and that the joint troubles only came on as the temperature was falling and as the cardiac and general symptoms were improving. As a rule a gonorrhœal discharge renders the diagnosis easy, but in women this may not be so, as the import of a vaginal discharge may readily be overlooked or misinterpreted. It is most often mistaken for true rheumatism but the comparative absence of fever and its refusal to yield to the salicylates usually point out its true nature. Sometimes it may be confused with rheumatoid disease, more especially should it affect, as it may rarely do, the temporo-maxillary joints. It must not be forgotten also that in gout there may be a urethral discharge of a non-specific nature. However, as a rule, the joint trouble is so distinctive as to lead to little or no confusion.

Scarlatinal arthritis is a type of arthritis seen in several other infectious diseases. It is usually seen in severe cases and in adults and appears most often just as the rash is disappearing. It may affect several joints and may be so severe as to suppurate, but this is not common. The elbows and knees are the joints most frequently affected, and it has a greater tendency to affect the smaller rather than the larger joints and those of the upper rather than those of the lower extremities. As a rule the disease yields rapidly to the salicylates. This infectious form of disease is not one often seen at a balneological resort, but now and then we come across cases which have their origin in the poisons of infectious fevers and which have persisted for long periods. It is also of interest on account of the frequency with which scarlatinal and rheumatic patients develop chorea, possibly pointing to an intimate relationship between the two diseases. If we accept the discovery of a diplococcus (by Dr. W. J. Class[5]) as the specific cause of scarlet fever one is tempted to ask what is the relationship of this diplococcus to that of rheumatism as described by Dr. Poynton and Dr. Paine. It would be of great interest to know what their reaction is one upon another and what their influence was on each other's growth and virulence, and what influence they had on the production of chorea. Do their toxins when inoculated into the central nervous system produce choreic movements? Given a micro-organism as the cause of scarlet fever it is probable that the joint troubles are originated by the organism itself. Where suppuration occurs we know that pyogenic organisms must have reached the joints. If they, why not the others? If suppuration occurs it is almost certainly due to secondary infection and it is in such cases that the streptococcus pyogenes has been found. Class's micro-organism does not cause suppuration and it seems almost certain that the streptococcus is only an accidental secondary infection.

Malaria, to turn to a subject which is exciting at present a good deal of interest, is frequently associated with arthritic changes. In malarial cases I have seen joint troubles in two forms—one obviously due to true rheumatism and contracted probably at the same time as the malarial poison; the other form is rarer and occurs apparently as an integral part of a malarial attack. Two cases of the latter variety some time ago presented themselves to me. Both patients were in the army and their malaria had been contracted in Burma. They had never served in the Mediterranean. When first seen there were no arthritic symptoms, but they were both subject to malarial attacks at more or less irregular intervals. They had for some time past been subject to joint pains during these attacks and had therefore come to Bath to see what we could do for them. Soon after coming under observation they had attacks of ague, going through the cold, hot, and sweating stages, but as the temperature fell the patients complained of pains in the limbs and joints, the joints most affected being the knees, elbows, wrists, and ankles. The joints became somewhat swollen and painful and remained so for possibly two or three days. Muscular pains accompanied the joint ones but were not so severe or so marked. There were no cardiac troubles but there was anæmia and splenic enlargement. During the time they were under observation each patient had from three to four such attacks and on each occasion presented somewhat similar symptoms, but towards the end of their term here the arthritic symptoms did not seem quite so marked or so severe. However, they were by no means cured and I found treatment unsatisfactory. As the occurrence of joint troubles in malaria is, I believe, somewhat rare, the question arose as to the exact nature and cause of the attacks. In neither case was there any suspicion of Maltese fever and the history of the onset of the disease in Burma was quite distinct. As we know that in Maltese fever joint troubles occur due to the micrococcus melitensis it occurred to me that possibly a somewhat similar condition might exist in Burma, but I can find no history of any such disease. The attacks in my patients differed to what occurs in Maltese fever, where the joints are only affected some time after the onset of the fever and where they are also associated with a good deal of muscular pain and neuralgia.

Another point of interest is that the malarial poison seems to affect adversely the curability of both gout and rheumatism. These two diseases, when seen in malarial subjects, usually present themselves in most intractable forms. Often a gouty attack will determine one of ague and *vice versâ*. Another thing I have noticed is that in some cases, if quinine be freely administered for the ague, it seems to bring on an acute attack of gout. So much so is this that many patients tell me they can never take quinine without bringing on gouty symptoms. This is especially marked with the sulphate and hydrochlorate of quinine, much less so with the salicylate. The reason for all this seems quite unknown and I merely mention my own observations in the hope of drawing attention to certain points worthy of further investigation.

A disease, pulmonary osteo-arthropathy, may give rise to some little difficulty in diagnosis, principally owing to its rarity. It is most likely to be confounded with acromegaly, but in the latter disease there is no alteration of the nails nor are the finger-ends clubbed nor the carpus and metacarpus much thickened. The chief characteristics of the disease are great enlargement of the hands, wrists, feet, and ankles, associated with, and secondary to, some chronic pulmonary affection, such as phthisis, chronic bronchitis, and empyema. In the joints the changes are effusion with enlargements and ulceration of the cartilages and articular ends of the bones. Marie is of opinion that these changes

[5] THE LANCET, Sept. 29th, 1900, p. 927.

are due to toxic poisoning, but Thorburn looks on them as tuberculous. The evidence either way is slight and indefinite.

Recent research in gout seems to have done little but upset all our former ideas as to its pathology and origin. Not so long ago it seemed as if we had arrived at some common agreement on the subject, but every division of it has recently been re-investigated, with the result that all our old theories have been found wanting, and the new ones brought forward are so diverse and uncertain that it is apparently impossible to formulate any satisfactory theory. After perusing much literature on the subject I find that about the only fact which seems tolerably certain is that uric acid, or its derivatives, is the immediate cause of the joint troubles. But why uric acid should be deposited in these positions, why there should be an excess of uric acid in the blood, if such excess exists, and why it should not be excreted as is done in other conditions, seem to be still *sub judice*. It appears to me that something more than excess of uric acid is necessary, and the theory of a toxic condition of the blood or tissues being the determining agent, seems from one's experience to be the most likely solution of the difficulty. All experiments on the healthy subject have failed to bring about the gouty state, and therefore it seems as if in gout the blood or tissues acquired some peculiar characteristic, with the result that some ingredient of the blood which in the natural state would be excreted without any symptoms becomes a poison capable of causing acute joint troubles. So much, however, is pure speculation that I do not care to enter further into the subject here.

Questions of diagnosis between certain irregular and chronic forms of gout and some forms of rheumatoid arthritis and subacute and chronic rheumatism offer the most common difficulties we who practise at bathing resorts have to consider. The acute forms of the various diseases are so characteristic as to give rise to no trouble. It is as gout passes from the acute into the chronic and more irregular forms, or where it has never been acute, that diagnostic difficulties arise. Especially is this so in middle-aged or elderly women, and it is often only after prolonged and patient observation that a definite diagnosis is possible. Yet from the point of view of treatment this is all important. Gout is more common in men, but a certain number of cases occur in women, usually of a chronic irregular form. It mostly occurs in the well-to-do and well-nourished. In irregular cases it does not occur suddenly, nor is the onset acute, but possibly there is the previous history of such an acute attack. It is seldom symmetrical, almost never affects the temporo-maxillary joints or back of the neck, and is much more liable to affect the joints of the lower limbs than those of the upper. Owing to the deposits of the biurate in the joint structures the latter are often irregular in size and shape, sometimes being nodular, but they may present almost any appearance. There is no tendency to destruction of the tissues. It is often associated with digestive troubles and irritability of temper, as well as marked depression of spirits. The teeth are usually ground down, whilst the nails may be cracked and marked longitudinally.

Chronic rheumatoid arthritis is more common in women than in men, and amongst the poor and badly-nourished. It usually begins insidiously in one of the metacarpo-phalangeal joints and is not associated with redness or great tenderness. It rapidly spreads to many other joints, giving rise to much crippling and deformity. It is specially liable to affect the temporo-maxillary joint and the back of the neck. There are marked muscular atrophy and often pigmentary and vaso-motor changes. Once a joint is affected there is little tendency to improvement. There is marked symmetry in the joints attacked, but the first symptom can usually be traced to one side. There are no biurate deposits, although lipping and outgrowths may be mistaken for them. The cartilages are ulcerated and there may be much coarse grating. It is not readily affected by the salicylates. Chronic rheumatism never affects the temporo-maxillary joints and is not associated with the formation of bony or cartilaginous deposits in the joints. It exhibits little symmetry and is not progressive. It is usually associated with rheumatic pains and yields to the salicylates in a marked degree.

In certain nerve diseases arthritic changes are noticed and of these tabes may be taken as a type. These changes do not give rise to much trouble in diagnosis, and it is more from the point of view of origin that they are of interest. In them the joint troubles are the result of trophic influences, which alter the joint's nutrition to such an extent as to give rise in some cases even to acute inflammation, but more frequently only to a chronic condition characterised sometimes by much tenderness, at others by none, by ulceration of the cartilages, by fibrous adhesions, and by alterations in the articular ends of the bones. In all such cases a condition of nerve degeneration exists, the result of some serious organic lesion of the nervous system. This degeneration has been found in every case in which it has been looked for, and it has even been found in the nerves of the joints themselves. It was the absence of these changes which first threw doubt on the origin of rheumatoid arthritis, and it appears to me that this in itself is so strong an argument that one can positively say that rheumatoid disease, in the absence of nerve lesions, must originate in some other way.

Senile degenerative arthritis is essentially a monarticular disease, although in some few cases we see two or more joints affected. It is seen in elderly people, especially men, and in most cases as the consequence of some injury more or less trivial. The joint changes are unaccompanied by any vaso-motor or trophic changes, except such as are the result of general malnutrition or disease. Atrophy of the muscles of a limb may often be marked, but we never see any reaction of degeneration, and the muscles usually respond quickly to treatment. This, however, I am sorry to say, is not the case with the arthritis, which is persistent and, if left alone, progressive, ending in the loss of the use of the affected limb. The joints most frequently affected are the larger ones, especially the hip and the shoulder. The movement of the affected joint being limited and painful, the patient is inclined to save it as much as possible. There is grating almost invariably and often shortening. There is little or no swelling visible and no redness. Deep pressure always elicits pain, in the case of the hip most pain being felt in the groin and in the shoulder either in front or on the outer side of the joint. The joints show thickening and chronic inflammatory changes of the synovial membrane, whilst the articulating surfaces are worn down, the cartilages being destroyed in patches and the bone being soft and yellowish from fatty degeneration and absorption of its structure. It presents all the characters of a local progressive degeneration.

It will thus be seen that as our knowledge at present stands arthritic troubles arise in a great variety of ways. There are those due to (1) bacteria themselves acting on the joint structures; (2) bacterial poisons (pulmonary osteo-arthropathy); (3) toxic poisons of as yet an undetermined character (gout); (4) nerve degenerations; and (5) senile degenerations. Of these Nos. 2 and 3 will probably be referred to some other category as further scientific data become available.

Bath.

ON PROTECTIVE INOCULATION AND SERUM-THERAPY.[1]

BY J. L. BUNCH, M.D., D.Sc., M.R.C.P. LOND.

IN speaking to-night of the subject of serum-therapeutics I am speaking of a subject which is now essentially practical—a subject which is no longer of exclusive interest to the bacteriologist and to the purely scientific worker, but one which is of far-reaching importance both to the medical practitioner and to the patient. Within the last few years the treatment of some of the acute infectious diseases has undergone considerable modification and augmentation, with the result that the prognosis has been greatly improved and the mortality, more especially in diphtheria, to a marked degree diminished.

By the injection of certain antitoxic sera it has been found possible to render less fatal and to cut short the attacks of some of the most dreaded diseases, and even, by the methods of protective inoculation, to render the individual insusceptible to certain diseases and artificially to confer on him a more or less permanent immunity. Such immunity or power to withstand the attacks of certain infectious diseases which to others are destructive belongs

[1] A paper read before the North London Medical Society on Feb. 14th, 1901.

from birth to some individuals and to some species of animals, and such an inherited or congenital immunity is to be distinguished from the artificially produced or acquired immunity. Thus congenital immunity against syphilis, scarlet fever, and measles is possessed by all animals except man; in other words, man is the only animal which is susceptible to these diseases. Again, fowls, rats, and pigeons are immune to anthrax, dogs are immune to tuberculosis, and rabbits to glanders. A still minuter subdivision as to susceptibility is seen in the case of mice, inasmuch as white mice and house mice are absolutely immune to tuberculosis and to glanders, while field mice are highly susceptible to both these diseases. In human beings every epidemic shows that some individuals, although equally exposed to infection with others, are not susceptible to certain diseases such as small-pox, measles, or scarlet fever, and it is well known that negroes are less liable to contract malaria and yellow fever than are the white races, though they are more susceptible to small-pox and tuberculosis.

This immunity can, however, be diminished or abolished experimentally. Thus, mere artificial disturbance of metabolism is capable of making animals otherwise immune to certain diseases susceptible to these diseases. It has been shown by Charrin and Roger that rats, which are usually immune to anthrax, lose this immunity after they have been sufficiently fatigued by forced treadmill work. Pasteur and Wagner demonstrated the fact that by artificially lowering the temperature of hens and pigeons, whose body temperature is normally 107° F., by means of baths, they became susceptible to anthrax, while, on the other hand, Gibier showed that by placing frogs in a bath heated to 95° they became liable to infection by anthrax, to which they were otherwise immune. Disturbance of metabolism by starving pigeons either before or directly after inoculation renders them also susceptible to anthrax. If the pigeons are starved for a period of less than eight days and then fed again on their normal diet they regain their lost immunity. In human beings great disturbance of nutrition, whether due to starvation or mental anxiety, also renders them liable to contract contagion in the course of epidemics, and to the latter cause we may also, perhaps, ascribe the frequent occurrence of tuberculosis among prisoners.

Acquired immunity to some diseases can be attained by passing through an attack of the disease, and it is frequently observed that an abortive or very trivial attack often confers immunity as well marked as that following a severe attack. Experimentally this has been often confirmed, and it has been shown that inoculation with a weak culture protects against subsequent inoculation with a virulent culture. The duration of the acquired immunity varies considerably and lasts a considerable time in the case of small-pox, scarlet fever, and measles, whereas in the case of diphtheria, pneumonia, and gonorrhœa, one attack gives, so far as we know, no protection against subsequent infection with the same disease, and in the case of malaria one would be disposed to say that each attack renders the patient more liable to subsequent infection.

As to the causation of immunity many theories have been advanced, and one of the earliest is that of Pasteur and Klebs, which assumes that in the first attack of the disease the substances in the body which are necessary for the growth of this particular organism are used up, so that similar bacteria which secure an entrance subsequently find none of the medium present which is necessary for their development. Against this theory are the facts that the fluids of a naturally or artificially immune animal frequently form an excellent artificial medium for the growth of the special micro-organism to which that animal is immune, and that sera which contain no bacteria are, when inoculated, capable of producing similar immunity.

The theory of Chauveau and Wernich assumes that micro-organisms during their growth produce substances which hinder their further growth and so not only bring the disease to an end but render the patient insusceptible to further invasion by the same bacteria. But the fact that immunity may persist for such long periods renders this theory also improbable.

A third theory, the theory of Buchner and Wolffberg, is based on Darwin's theory and makes the assumption that in small-pox and other infectious diseases the weaker cell-elements are destroyed and only those which are able to resist the specific organism which has caused the disease survive, and, further, that these cells transmit their acquired properties to their offspring, the organism, as a whole, being thus rendered capable of resisting further attacks of the specific disease.

A more widely held theory is that of Metschnikoff who first published his phagocyte theory in 1883. According to this theory certain white corpuscles of the blood and other cells derived from the mesoblast can take up and devour within themselves the invading bacteria. Thus, in the frog anthrax bacilli were seen to be taken up by the cells and to undergo peculiar changes quite different from ordinary degenerative changes, and Metschnikoff was able to obtain a culture from an anthrax bacillus which had thus been taken into a cell, the culture proving to be quite virulent. He found, too, that in immune animals when the bacilli were introduced beneath the skin but protected by means of a cotton-wool covering from the attacks of the phagocytes, they increased in numbers, whereas those bacilli which escaped from the protecting covering were promptly consumed. He assumed that as soon as any infection-producing organism attains access to the body it produces positive chemiotactic substances which attract the bacteria, but in proportion to its virulence it generates poisonous substances which paralyse the activity of the phagocytes and prevent them from devouring the bacteria. When an animal has been rendered artificially immune its phagocytes are able to resist this poisonous substance and to devour the bacteria before they have produced any considerable amount of poison.

In direct opposition to Metschnikoff's theory a theory has been advanced which ascribes to the cell-free plasma and serum of the blood bactericidal properties. Nuttall showed that not only the blood, but also pericardial fluid and aqueous humour of dogs have the property of killing anthrax bacilli. Behring further proved that anthrax bacilli grow well on the blood-serum of animals which are susceptible to anthrax inoculation but cannot be got to grow on the serum of white rats which have been rendered immune to anthrax. He also showed that while one particular serum is fatal to certain varieties of micro-organism it is powerless to inhibit the growth of certain other organisms, and that a definite amount of serum is only capable of dealing with a certain definite number of bacteria, so that if bacteria in excess of this number are introduced they grow and multiply actively. In other words, the immunity thus conferred depends upon the ratio between the number of micro-organisms and the quantity of the substance inimical to their growth contained in the fluid. The nature of these poisonous substances or "alexins" is but little known. They are extremely unstable and cannot be kept intact outside the body for any considerable time, and they are easily decomposed by sunlight and by warming. These alexins, or at any rate the serum which contains them, have a destructive action not only on bacteria but also on red corpuscles and on leucocytes of other species of animals. From these and other characteristics it seems probable that alexins are of the nature of proteids. According to Ehrlich the action of antitoxins is brought about by their chemical combination with toxins, much as an acid combines with a base. The French school, on the other hand, hold that the action is essentially a "vital" one.

Ehrlich has described the existence of a series of bodies or "toxoids," which, like toxins, have an affinity for antitoxin, but which differ from toxin in their valency for antitoxin. These toxoids can be divided up into three classes—the epitoxoid or toxone, in which the valency for antitoxin is less than that of the toxin; the syntoxoid, in which it is equal; and the protoxoid, in which it is greater. An attempt has been made to combine this last humoral theory with the phagocytic theory of Metschnikoff by supposing that the phagocytes do not themselves directly take into their substance and devour bacteria, but that they secrete the poisonous materials which are capable of inhibiting their activity and ultimately bringing about their death. Some experiments of Buchner afford strong confirmatory evidence of this theory. By suitable chemical stimulation he was able to cause the secretion into the pleural cavity of rabbits and dogs of leucocyte-containing exudations which possessed bactericidal powers stronger even than those of the blood or serum of the same animal. Under these conditions however, phagocytosis could be observed to be proceeding actively, and the question immediately arose as to how far the bactericidal qualities of the fluid depended upon phagocytosis and how far upon the contained alexins. This question was settled by freezing the fluid, and by this means killing the leucocytes but not injuring the alexins, and then again testing its bactericidal powers. These were found to be in no way

diminished, and, inasmuch as the leucocytes had been killed, the capacity of the fluid to destroy bacteria must necessarily depend upon the contained alexins. But even if phagocytosis is merely a secondary phenomenon, and the destruction of bacteria is brought about by poisonous substances circulating in the fluids of the body, there is a considerable amount of evidence which goes to show that these poisons are secreted by leucocytes. The influx, therefore, of these white corpuscles to an infected area means an increased secretion of substances poisonous to the invading micro-organism and increased powers of resisting disease, but according to this theory it is immaterial to the patient whether the disease be combated by thus inducing an active leucocytosis or whether a sufficient supply of the bacterium-killing substance which is normally manufactured by leucocytes be directly introduced into his tissues.

In discussing the practical application of these principles to the treatment of disease I would lay stress on the fact that the advances of science, like those of nature, are slow, and that the marvellous discoveries which are only introduced to the public in their completed form, and then appear, like Pallas Athene, to have leapt fully developed from the head of their creator, can, on closer examination, be traced through all the stages of their gradual development. Though, to the romantic imagination, the falling of an apple, the swinging of a church lamp, and the flowing of water from a bath revealed to Newton, to Galileo, and to Archimedes respectively the secrets of nature, nevertheless truth compels us to recognise that these secrets were only unravelled by ceaseless striving and by strenuous work, and that only by such means can future advances in the field of research be accomplished. Thus we can trace back to far distant times the first attempts at preventive inoculation. It was early recognised that certain diseases only occur once in the life of the individual and that he is in future protected against attacks of the same disease. From this it was but a short step to the artificial production of such diseases, especially when it was found that in the case of small-pox a mild form of the complaint could be induced by the inoculation of the contents of a pustule in a healthy subject, and that such an inoculation was as effectual a safeguard against the possibility of contracting the disease in future as a severe attack of small-pox resulting from contagion. It is probable that this method of artificially inoculating small-pox was known and practised thousands of years ago by the Indians and Chinese, and in the Middle Ages it was certainly a common practice. It was not, however, until the year 1721 that the method was introduced into England from Turkey by Lady Wortley-Montagu, the wife of the then English ambassador to Constantinople. It met with very considerable opposition, and rightly, for, in spite of its undoubted protective powers, individuals thus inoculated, even if they themselves only experienced a mild attack of the disease, formed each a focus from which others might become infected, and in these latter there was no certainty that the complaint would always run a favourable course. In 1798, however, Jenner published his account of the protective action of cow-pox against small-pox, a method which was already fairly well known, and of which a description had been given by Fewster and Sutton, but which had not as yet met with general acceptance—and it is well known that the application of this method as a result of Jenner's teaching has practically stamped out small-pox in those districts where the practice has been universally carried out. It must, nevertheless, be always remembered that the protection thus obtained is not permanent. The essential principle which underlies such vaccination is that when the disease is passed through animals which are little susceptible to it a vaccine is obtained which causes but slight reaction in the first species of animal and yet protects against the disease. In an exactly similar way to Jenner's small-pox method the virus of the swine fever when passed through rabbits gives rise to an attenuated virus which in swine is protective against swine fever, and the employment of this vaccine has enabled epidemics of swine fever in some localities to be stamped out. Attenuated cultures which can be used as vaccines can also be obtained by exposing the cultures to temperatures above those at which they grow best, by exposing them to sunlight, increased pressure, or electricity, or by the addition of chemicals such as carbolic acid. Thus anthrax vaccine is obtained by growing the cultures for different periods at a temperature of 43° C., and inoculating first a weak culture and then more virulent ones. By this means the mortality from anthrax for two corresponding periods of three years was in one country reduced from 2·3 to 0·5 per cent.

The method of attenuating cultures by means of drying is made use of in the treatment of rabies. Pasteur showed that the introduction of a portion of the central nervous system of a mad dog beneath the dura mater induced rabies, also that the unknown virus could be increased in virulence by passing through rabbits. After a virus of maximum virulence has been obtained it is attenuated by drying over caustic potash and for each day of drying it loses an appreciable amount of virulence the extent of which can be foretold. Thus an emulsion of a spinal cord which has been dried at a temperature of 72° C. for from one to four days causes rabies seven days after inoculation; a cord which has been dried for five days does not produce any symptoms until after a still longer period; while a cord which has been dried for 14 days produces no symptoms. The patient under treatment is first inoculated, if the case is not an urgent one, with a weak virus, and afterwards with vaccines of increasing virulence, so that he becomes immune against subsequent inoculation with even large doses of the same virus and against subsequent manifestations of symptoms of rabies even if he had become infected before the treatment was commenced.

Instead of inoculating with attenuated cultures of micro-organisms protective inoculation can in some cases be attained by injecting the products of metabolism of these micro-organisms which are formed during their growth, or again by inoculating bacteria of a different kind or even extracts of the bacteria themselves. Of the latter the best known is tuberculin, which is essentially a watery or glycerine extract of tubercle bacilli and contains bacterial proteins. The bitter disappointment to which tuberculin has given rise depends largely on the fact that its action is not specific, but merely resembles that of proteins obtained from other bacteria. This action has been described by Buchner as consisting of cell proliferation, leucocytosis, increased lymph secretion, and, in man, of inflammation either round the site of inoculation or, in the case of the easily absorbed tuberculin, round those spots where a considerable number of tubercle bacilli happen to be situated. Not only can such a reaction be obtained by the injection of proteins other than those derived from tubercle bacilli, but also from bodies varying largely in chemical composition, such as kreatin, kreatinin, acetone, and taurin. A further proof that the action of tuberculin is not specific is that it produces the same local reaction in infectious diseases which are not tuberculous in origin, such as actinomycosis and leprosy. Tuberculin has, of course, a certain favourable action on some cases of tuberculosis, inasmuch as it induces inflammation round already diseased foci, and so leads to the death of the tubercle bacilli, but this is in most cases not sufficient for the cure of lung tuberculosis, because the infection is a mixed one, and streptococci and other organisms are also present. In fact, the latter stages of lung tubercle are practically stages of septicæmia. Streptococci and staphylococci are present in large numbers in the blood and the case is far beyond the power of tuberculin or anything else to cure. As a method of diagnosing tuberculosis in cattle tuberculin has been freely used. Bang of Copenhagen reported that in Denmark out of 8401 animals 3362 reacted to tuberculin, but, as it was impossible to kill off all the infected animals the method was adopted of taking the calves from their mothers and from the stalls as soon as they were born and feeding them on boiled milk. Injections of tuberculin some weeks afterwards gave no reaction in these same calves, so it seems that the remedy was effectual. As to how much importance we must attach to the question of the conveyance of tuberculosis by milk I do not now propose to inquire, but in this connexion I may quote a recent statement by Dr. Poore, that in a herd of cows belonging to one of the most illustrious families of the kingdom 38 out of 40 cows were found to be tuberculous, and yet there are three generations of this family living, and no family is more free from the infection of tuberculosis. A protein body similar to tuberculin is mallein, which is obtained from the bacillus of glanders and is used in the diagnosis of glanders in animals. Here, again, its action, like that of tuberculin, is not specific, as has been abundantly shown experimentally.

The attempts to bring about satisfactory protective inoculation which have attracted most attention recently are undoubtedly those connected with typhoid fever. In the case of soldiers proceeding to the Cape it was certain that

many of them would be exposed to infection from enteric fever, and by inoculation of a small amount of a dead culture of the typhoid bacillus it was hoped that they would be protected against infection from enteric fever and an "active" immunity to the disease established. The following method was employed by Wright of Netley. A virulent broth culture of the bacillus is grown at 37° C. for about a fortnight and is then kept at a temperature of 60° C. or more until it is sterilised, and a quantity of lysol added equivalent to 0·5 per cent. On decanting the contents of the flask a clear sterile fluid is obtained which contains the soluble more or less poisonous substances formed by the bacteria during their growth and also the soluble remains of the bacteria themselves. Subcutaneous injection of five cubic centimetres of this fluid will kill a guinea-pig weighing 250 grammes in less than 20 hours. The amount used for the inoculation of human beings is two-fifths of the quantity which would be fatal to a guinea-pig weighing 250 grammes. A second dose of double the quantity may be given a week afterwards. The injection may be given in any spot where the subcutaneous tissue is loose, and Foulerton recommends keeping the patient at rest for the next 24 hours after inoculation. The symptoms following inoculation he describes as consisting of frontal headache, shivering and even rigors, syncope, and shooting pains. The lymphatic glands enlarge, and there are œdema and cellulitis round the site of inoculation, coming on about 18 hours after vaccination at the time when the other symptoms are disappearing. The temperature rises very soon after the injection and attains its maximum about 12 hours afterwards, but it very soon falls again to normal. In a patient, on the other hand, who had been already infected with typhoid fever five days before vaccination only an insignificant rise of temperature occurred as a result of the vaccination. Such an injection, then, of a dead culture of the specific bacillus protects against subsequent infection with the same bacillus, and the serum of the inoculated person acquires at the end of the week curative powers, and also agglutinative powers greater than those conferred by passing through an attack of typhoid fever. Thus, the agglutinative action can be obtained with the serum of an artificially immunised animal even when it has been diluted 1000 times, while the serum of a patient who has recently recovered from an attack of typhoid fever will not react when it is diluted more than 300 times. It has also been shown that the serum of a patient convalescent from enteric fever has less power to confer passive immunity on a guinea-pig than the serum of an artificially immunised animal. When a patient has been inoculated, his serum should be examined a week afterwards, and the inoculation cannot be considered satisfactory unless clumping occurs quickly with a dilution of 1 in 50. Foulerton found that 45 per cent. of some cases which he examined as long as two years after inoculation still showed a definite reaction.

The statistics dealing with the results of anti-typhoid inoculation are as yet very meagre. Wright published last year a report dealing with some 11,295 individuals in India, of whom a quarter of the number were inoculated against typhoid fever. Of the inoculated, 0·95 per cent contracted typhoid fever, as against 2·5 per cent. among the uninoculated; the mortality among the inoculated only amounted to 0·2 per cent., while among the uninoculated it reached 0·34 per cent. On Feb. 9th, 1901, Wright published the official report dealing with the effects of anti-typhoid inoculations in the 15th Hussars, stationed in India between October, 1899, and October, 1900. 539 out of 718 were inoculated, and among these the incidence of typhoid fever was represented by 0·55 per cent. and the mortality by 0·27 per cent.; while the incidence in the uninoculated was 6·14 per cent., and the death-rate was 3·35 per cent. Assuming that some of the inoculations were unsuccessful, as they almost certainly were, these figures are distinctly in favour of inoculation, but there is still a certain lack of unanimity in praise of the treatment, and Ryerson has reported the case of an officer at the Cape who was inoculated twice and yet developed the disease. In any case further statistics are necessary before any definite conclusions can be satisfactorily arrived at.

Various methods of protective inoculation can, then, be employed, some with greater success and some with less, but the "active immunity" which is thus brought about is not an instantaneous affair—it requires a certain time for its accomplishment, it cannot be hastened, and it must be performed before the patient has become infected with the disease. In the case of rabies it is true that the disease can be arrested if protective inoculation is employed during the incubation period, but the method of action of the inoculated virus is totally unknown and we are absolutely in the dark as to how far this method is analogous to the others which I have described.

It is, however, the question of cure or arrest of an already developed infectious disease which to us has the greatest interest, and it is with the name of Emil Behring that we must associate the chief advance in this direction. Other observers, and notably in our own country Sidney Martin, have advanced our knowledge of serum therapeutics very considerably, but it was in 1890 that Behring first published, in conjunction with Kitasato, his researches on diphtheria immunity. He showed that the blood and cell-free serum of animals which had been artificially rendered immune to diphtheria and tetanus possessed the power of rendering harmless the poisons which these bacilli generated in their growth. Thus the serum of a rabbit which had been rendered immune to diphtheria by infection of attenuated diphtheria cultures was able to protect other animals against diphtheria even when they had developed marked symptoms of the disease. The action of this antitoxin was so undoubted, the method so simple, that its application to diphtheria in man followed quickly, and the work of Ehrlich and others soon made it possible to calculate the potency of the serum and the exact amount of the dose necessary. Although the antitoxin was capable of neutralising the toxin generated by the bacilli and circulating in the blood-stream it had no power to destroy the bacilli; these still grew at the point of infection, but the changes which had been brought about by the injection of the serum caused the localised process to be shut off from the possibility of spreading and the animal to become insusceptible to the action of the diphtheria poison. It is of the greatest importance to remember that antitoxin serum has no reparative action, nor can it regenerate cells which have already undergone katabolic pathological changes, and, moreover, that a certain amount of antitoxin can only neutralise a certain fixed amount of toxin. It follows from this that it is necessary to commence the treatment at the earliest possible moment when there is a minimal amount of toxin already in the circulation, and seeing how innocuous its employment is, a large dose of serum should be given at the earliest possible moment in every case of diphtheria. An initial dose of not less than 6000 units should be injected subcutaneously, with, of course, antiseptic precautions, and this should be followed by a second dose if necessary. Roux and Martin showed that if streptococci were injected with the diphtheria serum the disease ran a far more deadly course, and, in the case of animals, if treatment was not commenced within six hours of the onset of this mixed infection, the animal infallibly died. Where, however, pure anti-diphtheritic serum was employed, and a sufficient dose was injected into the animal, it was found to be absolutely protective against subsequent infection with diphtheria, and, even if the dose of serum was too small to be quite efficient, the disease took longer to develop and the animal only died at the end of several weeks. In man the employment of anti-diphtheritic serum has given excellent results. Thus Sidney Martin and Hunt showed that in University College Hospital, for the years 1896 and 1897 its use had reduced the mortality of diphtheria from 28 per cent. to 17 per cent., and the report of the Metropolitan Asylums Board for the year 1899, dealing with some 7000 cases in the year, gave the mortality of cases treated with antitoxin as 15·38 per cent., and of all diphtheria cases, both those treated with antitoxin and those not, as only 14·05 per cent.

The treatment of plague by means of antitoxin serum has proved most successful in the hands of Calmette and some other observers. Thus, at Oporto during September, October, and November of last year 142 patients were treated with serum and only 22 died. The mortality amongst those treated with anti-plague serum was therefore only 15 per cent., as compared with 63 per cent. among those not so treated. The serum used was obtained by injecting into horses first cultures of plague bacilli killed by heat and afterwards living and virulent cultures. After an active immunity had been established in the horse some blood was drawn off and the serum was heated for a time to 58° C. The alexins of the serum are destroyed by this temperature, so that only the "reacting substance" is injected into the patient, which acts upon the leucocytes in proportion as the serum is absorbed, in conjunction with the natural alexins

of the body. But it is very important that these two processes shall go on at the same time and as rapidly as possible, so Calmette insists on the necessity of injecting the serum directly into the circulation. 20 cubic centimetres of anti-plague serum are injected into a superficial vein of the patient's hand, forearm, or leg as soon as a case of plague is suspected without waiting for the results of bacteriological examination. If the fever does not subside completely in 24 hours, and if the diagnosis is confirmed, another injection of 20 cubic centimetres of serum must be given into a vein. These injections are absolutely harmless, and if care is taken to warm the serum to body-temperature before injection the patient experiences no discomfort from the injection. Serum injection is equally efficacious for the prophylaxis of plague in localities already infected, but unfortunately the protection afforded is not a very lasting one, and the injection must be renewed at the end of a week. Prophylactic injections need not, however, be given intravenously; a simple injection of 10 cubic centimetres under the skin of the abdomen is quite efficacious. Above all, the serum presents the immense advantage of conferring immunity in a few hours, so that we have here a method of treatment which may not only prove to be of great service in the prevention of plague, but also in arresting its progress when it has already developed.

Antitoxin treatment has also proved of service in tetanus, typhoid fever, and snake-bite, and there is every reason to hope that in the future we shall, by its means, be still further able to control and cure those few cases of infectious disease which have not been entirely prevented by suitable protective inoculation.

Wimpole-street, .

PERSISTENT METRORRHAGIA.[1]

BY J. INGLIS PARSONS, M.D. DURH., M.R.C.P. LOND.,
PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

THERE are certain well-recognised causes for metrorrhagia, such as fibro-myoma, polypus, retained products of conception, diseased appendages, cancer, &c. These cases are usually recognised and their treatment is fairly well defined if some differences of opinion are allowed for. It is not my intention to discuss these obvious causes now, but to consider another class of case which is not very uncommon and about which very little is said in the text-books—I mean metrorrhagia which is not brought about by any of these causes and for which, in fact, there is no obvious cause. Even when we examine these patients under an anæsthetic we fail to find anything wrong in the pelvis, and when we dilate the uterus there is nothing apparent to account for so prominent a symptom.

Under these conditions the indication is to use the curette. If the endometrium which is scraped off is found to be thickened the curetting does good and the metrorrhagia usually stops, at any rate for some months. On the other hand, in a certain number of cases we find very little thickening of the endometrium, and then the metrorrhagia will often persist and perhaps be worse after the curetting than before. In such cases I have been able to stop the hæmorrhage permanently by the use of the constant current. I wish to advocate this method of treatment in preference to the risk and mutilation involved by hysterectomy. As I have never removed the uterus for this condition I cannot say much on the pathology of the subject beyond some observations on the morbid anatomy of the endometrium obtained by curetting.

With the first class of case, which is the most common and which usually gets wells after curetting, we find under the microscope that the endometrium is considerably thickened by an excessive glandular proliferation. With the second class of case, which I am more particularly dealing with and where the metrorrhagia persists after curetting, we find a proliferation of the connective tissue in the endometrium, while the glands may be decreased in number. The condition, in fact, corresponds to that described by Wyder of Berlin as "interstitial endometritis" and which he found to be present in the endometrium of bleeding myoma.

When curetting, the use of ergot, and other methods of treatment failed I decided to try the effects of the constant current before doing hysterectomy. As I have seen some of the worst cases of hæmorrhage from fibro-myoma become perfectly regular and remain so for years from the use of electricity properly applied I expected and obtained just as good results in these cases. The similarity in the morbid condition of the endometrium to myoma rendered it probable that electricity would be effective. Another reason in its favour was that the cavity of the uterus is not distorted in shape as it often is in fibro-myoma, consequently it is much easier not only to pass the electrode but also to apply it thoroughly to the cavity of the uterus. In the two cases which I bring before you as examples the hæmorrhage was completely stopped by the constant current, although curetting and all other treatment had entirely failed.

The applications are made by means of a platinum electrode, with a moveable insulating sheath. This is passed up to the fundus of the uterus, while the insulating sheath is adjusted so as to reach just beyond the internal os. As the bleeding comes from the body of the uterus it is absolutely essential to success to see that the current comes off in the body of the uterus and not in the cervix. A clay pad is placed on the wall of the abdomen just above the pubes and connected to the negative pole, while the intra-uterine electrode is connected to the positive pole. At the first application only a mild current should be used, not more than 50 milliampères, subsequently it can be slowly raised until the galvanometer indicates from 75 to 100 milliampères. This is kept on for 10 or 15 minutes. The patient need not lay up during the treatment and except in extreme cases can come to her medical man's house for the treatment. The applications are made twice a week. An antiseptic vaginal douche should be used every day, morning and evening. I need hardly say that the electrode must be absolutely clean and should be placed in an antiseptic solution like any other instrument before being used for operation.

The number of applications required will vary according to the severity of the case. Whatever the number required to reduce the loss to normal proportions, half that number must in addition be given in order to produce a permanent result. The treatment is suspended for a week during menstruation and if at the end of that time the loss has not stopped it should be disregarded and the treatment continued. In some of these cases where the loss is persistent and never stops there is some difficulty in knowing the proper date for menstruation. By closely questioning the patient we shall generally elicit the fact that for one week every month the loss is greater than during the other three weeks. We may take that as an indication of the normal time for menstruation. As a rule no improvement begins until several applications have been made, then the loss begins rapidly to diminish. With a current of 75 milliampères properly applied and slowly raised the patient feels very little, if any, pain. The sensitiveness of the uterus which is usually present at first goes off after two or three applications.

CASE 1.—A woman, aged 32 years, was admitted into the Chelsea Hospital for Women on Dec. 17th, 1898, complaining of profuse loss at the periods, which had so weakened her that she was unable to earn her living. She had had one child five years before and up to that time there was no difficulty with menstruation. Since the birth of the child the loss had gradually increased until she used from 30 to 40 diapers, while the interval was less than formerly. There was practically no pain during menstruation. She had never had a miscarriage. Her general health was good except that she felt very weak from loss of blood and was incapable of much exertion, although she used to lead a very active life. On examination the heart and lungs were found to be normal. The right kidney was slightly moveable. The uterus was found to be in position and not enlarged, and the mobility was unimpaired. The cervix was slightly eroded, with more discharge than usual. The appendages appeared to be healthy. On Dec. 22nd, under ether, the uterus was curetted and swabbed over with solution of perchloride of iron and tincture of iodine. On the 24th the loss still continued. On the 29th the loss stopped. On Jan. 9th, 1899, menstruation began, when the loss was worse than before and showed no signs of improvement. On Feb. 16th the first application of the constant

[1] A paper read before the Harveian Society of London on Feb. 7th, 1901.

current was made, 65 milliampères being used for 15 minutes with the positive pole in the uterus. In all 12 applications were made, the strongest current used being 100 milliampères and the weakest current 50 milliampères. In April for the first time for many years the patient had a normal period. It lasted only four days and she only used 10 diapers. She has remained up to this date perfectly well; she is in good health and is able to earn her living, and she never loses more than normal.

CASE 2.—A single woman, aged 35 years, was sent to me by Dr. J. Thoresby Jones in July, 1899. She had never had a child or a miscarriage. In 1898 she began to lose more at the periods and also had some loss between them. This continued to increase until she found it necessary to have something done. She was taken, in October, 1898, to one of the leading specialists in London who curetted the uterus. The loss stopped for two weeks and then went on as before. She waited for eight months, but as there was no improvement and she was becoming worse she consulted Dr. Jones who brought her to see me. I found her a stout, healthy, well-grown woman who had enjoyed good health until the metrorrhagia began. On examination the uterus was found to be in position and to be normal in size, the sound passing for two and a half inches without pain. There was no tumour to be found and the appendages were normal. There was no erosion of the cervix and very little white discharge. The bowels were sometimes confined. 23 applications of the constant current were made with the positive pole within the uterus, with an average strength of 75 milliampères, for 10 or 15 minutes at a time. The loss had completely stopped after 15 applications. Experience, however, has taught me that in these cases, as well as in hæmorrhage from fibro-myoma, it is necessary after the loss is stopped to go on with the applications for a month or so if we wish to produce a permanent result. After the treatment was finished menstruation ceased for three months and she had no loss at all. Since then she has been quite regular and loses very little.

I will not weary you with any more cases, as these two are typical of the condition. The cause appears to be obscure. I was at one time inclined to think that the disease dated from a miscarriage, but the patient in Case 2 had never had a child or a miscarriage. There is, however, one factor in common with all these cases—viz., that the patients are either single or that, if married, they have remained sterile for some years. Now this is what we also find precedent to the appearance of fibro-myoma. In fact, my colleague, Mr. J. Bland-Sutton, states that there is an excess of fibrous tissue in the walls of the uterus although there are no actual fibroid tumours.

The constant current would appear to stop the hæmorrhage by means of its caustic action on the endometrium and the hæmostatic effect of the positive pole. If a small current is applied with two fine needles to the web of a frog's foot and watched under the microscope coagulation and stoppage of circulation can be seen in the capillaries round the point of the positive needle, while at the negative pole nothing is to be seen beyond a collection of hydrogen bubbles. In addition to this hæmostatic action the muscular wall of the uterus is toned up by the current just as much as the voluntary muscles are when electricity is employed to restore their tone after temporary paralysis. In connexion with this it may be worth while to mention that several patients have remarked to me voluntarily that after the course of electricity the constipation from which they had previously suffered had disappeared, although the treatment had been given solely with the purpose of stopping menorrhagia.

There is one other course of menorrhagia which I should like to refer to—viz., retroversion. On several occasions patients have been brought to me for menorrhagia which persisted after curetting, and having found the uterus retroverted I replaced it and kept it in position with a well-fitting Hodge pessary. At the end of two or three months the menorrhagia disappeared without anything else having to be done. There are, of course, many cases of retroversion which give rise to no symptoms and require no treatment, but, on the other hand, there are also many cases where the condition makes a woman's life a misery to her. She complains of constant pain in the back, worse on walking, and if there is much standing with bearing-down pain. During menstruation the uterus is very tender and she can hardly bear to be touched and she often has a sickening pain when the bowels act. In addition to this in about 30 per cent. of these cases there is menorrhagia. To my mind if there is no erosion and nothing else to account for the hæmorrhage the first indication is to replace the uterus in its proper position and keep it there. With the large majority of patients the menorrhagia will then cease in two or three months; if it does not then curetting should be done. But I maintain that it is of no use to curette a retroverted uterus for menorrhagia unless we keep the uterus in its proper position afterwards.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ABSCESS DUE TO APPENDICITIS SIMULATING STRANGULATED INGUINAL HERNIA.

BY J. B. PIKE, M.R.C.S. ENG., L.R.C.P. EDIN.,
HONORARY SURGEON TO THE LOUGHBOROUGH GENERAL HOSPITAL.

LATE in the evening of Jan. 7th I was requested by Dr. G. Cardno Still of Shepshed to meet him in consultation as to a case of abdominal obstruction. I am indebted to Dr. Still for the history of the case up to that time and for permission to send it for publication.

The patient was a fairly-nourished man, aged 35 years. About three years ago he had a bad attack of pain and vomiting, a repetition of previous slighter attacks, and some six months after this, when he had been sneezing, he noticed a lump in the right groin, which receded when he lay down, unless he happened to be lying on his right side. On Jan. 5th he was seized with severe pain and vomiting, which during the next day became stercoraceous. This continued, with complete obstruction, until the afternoon of Jan. 7th, when after an injection he passed some scybalous masses, fluid fæces, and wind. On the evening of this day, when I saw him, he was lying flat on his back, had a very quick running pulse, a distended and somewhat tender abdomen, and a distinct fulness in the right inguinal region. The external ring on that side could not be distinctly felt and the canal gave the impression of being filled with a small oblong mass with rounded edges along which no impulse was conveyed on coughing. It seemed imperative to explore this tumour, and for that purpose the patient was removed to the Loughborough Hospital. Ether was given and it was now possible to make out the external ring and that some substance was blocking the canal. The right side of the scrotum was noticed to be reddened. The condition of the patient now became so alarming that operation was reluctantly abandoned, and, fully recovering from the anæsthetic, he died a few hours after.

A partial post-mortem examination was made with the following result. The inguinal fulness and the scrotal blush still remained. On laying open the inguinal canal a somewhat dense sac was found, and on this being opened pus flowed out in large quantity. The sac was occupied by the thickened and infiltrated spermatic cord and there was no trace of bowel or omentum. Through the internal ring there was a communication with a large perityphlitic abscess, evidently due to appendicitis. There was general peritonitis and it was evident that a perforation had taken place on the 5th, which admitted pus into the peritoneal cavity. The sequence of events was therefore appendicitis, chronic abscess bursting into the inguinal canal and simulating hernia, perforation, and peritonitis.

The case is chiefly interesting from a diagnostic point of view. The anomalous points were that the swelling recurred on lying on the right side and that symptoms were not much relieved by the effect of the injection. These were, so far as I can see, the only things which made strangulated hernia improbable, as latterly the swelling was irreducible. No doubt the recurrence of swelling when lying on the right side was due to the pus gravitating down the canal when it became a low-lying point. Whether I should be able to

diagnose a second case of this nature I doubt, but I think the history of it gives some points of diagnostic value.

Loughborough.

A CASE OF AUTO-VACCINATION.

BY GEORGE H. ORMSBY, M.R.C.P. IREL., &c.

THE accompanying illustration shows a novel effect of vaccination on a patient at present under my care.

A married man, aged 45 years, while at work on Sept. 14th, 1900, got a slight scratch on the outer angle of the right eye. About a week previously I had vaccinated his child. His wife being ill he was obliged to take the child at night, the result being that matter from the arm inoculated the scratch. I first saw him on Sept 24th and the following day had a photograph taken. His eye was completely closed

and was very painful and irritable. His symptoms the same night were so suggestive of septic poisoning that I asked Mr. F. MacDougall to see him with me. By the following morning, however, he was much better and continued to improve steadily. The dark ring round the eye is owing to its being painted with iodine.

Mr. MacDougall tells me that during his extensive experience as "public vaccinator" he has never seen a similar case.

Runcorn.

NASAL DIPHTHERIA MASKED BY MEASLES.

BY WILLIAM WYLLYS, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.

I HAVE had under my care a patient whose illness in some respects resembled the case of diphtheritic paralysis reported by Dr. A. J. Rice Oxley[1] where only a slight sore-throat had been complained of and some difficulty had been experienced in diagnosing the condition of the patient. My patient, a boy aged five years, had been suffering from a typical attack of morbilli, his little sisters, aged three and two years respectively, being at the same time similarly affected. The only suspicious circumstance was the protracted and obstinate nature of the nasal catarrh, which was purulent, and in the case of the elder girl had existed for two weeks prior to the appearance of the measles rash. In no instance was sore-throat complained of nor was any membrane found in the fauces. The two girls made a perfect and permanent recovery, but the boy about a week after the subsidence of all symptoms and signs of measles became so weak and debilitated that I ordered him back to bed. In a few days, however, he appeared better and was allowed to get up, and as the weather was fine he was able to go out of doors about a week later, when he walked to my house though still obviously weak. Ten days afterwards his father carried him to me, as he said that the child seemed to have lost the use of his legs, toppling about when trying to walk, and that his head drooped to the left side. I accordingly once more ordered him to bed, and on my visit next day I found that he had a cough of a clashing, hollow character, which was quite ineffective in bringing up any phlegm, though after repeated paroxysms he retched and expelled mucus and food through his nose. My suspicions being aroused I examined his palate and found it to be paralysed as were also the muscles of extraordinary expiration. The patellar tendon reflexes could not be elicited and his pupils were dilated and sluggish to light. His expression was vacant and there was left internal strabismus. Bronchitis supervened, and though of itself not of a serious character it was rendered so by the impaired expiratory power. The boy's condition soon became critical, the repeated paroxysms of cough, coupled with the sitting posture occasioned by orthopnœa, telling severely upon the circulatory system. The treatment consisted of gradually increasing doses of liquor strychniæ and liquor ferri perchloridi three times a day and friction of the chest muscles with camphorated oil. Under it the child's condition improved so much that in three weeks he could sit up comfortably in bed and play with his toys. Two further attacks of catarrhal bronchitis occurred and, though obstinate, were satisfactorily dealt with by stimulant expectorants and the use of the steam-kettle. The boy's hearing was markedly impaired on both sides during convalescence, but gradually improved, as did his power of deglutition, and the "twangy" nature of his voice diminished. As paresis of the chest muscles persisted and the legs were much wasted, and the knee-jerks were still absent at the end of six weeks, massage for 30 minutes followed by galvanism was employed once a day for a fortnight and a rapid improvement was soon manifest, the boy's respiration becoming more natural, and, the use of his legs returning, he was able to walk a little, though in a tottering way. A year has elapsed, and he now enjoys very fair health except for occasional bronchitic attacks. He walks and runs well, his hearing is normal, he speaks with but a slight nasal twang, the thoracic movements are good, the knee-jerks have returned though only in a minor degree, and the strabismus is only obvious when he is over-tired.

The chief interest in this case centres in the fact that the patient undoubtedly had nasal diphtheria coincidently with measles, and that although his sister had a far worse purulent nasal discharge both during and before her attack of measles she developed no post-diphtheritic paralysis. The rarity of the concurrence of diphtheria with measles makes these notes worth publishing.

Great Yarmouth.

[1] THE LANCET, Feb. 2nd, 1901, p. 321.

INFECTIOUS DISEASES NOTIFICATION ACT.—At Falmouth on Feb. 11th a man was fined £1 3*s*. 6*d*. for not notifying that his child had scarlet fever. The medical officer of health stated that three other cases of fever were traced to this one. The defence was that a medical man was not required for such a trifling case.

PLYMOUTH MILK SUPPLY.—At the meeting of the Plymouth Borough Council held on Feb. 11th it was decided that the medical officer of health be authorised to issue annual certificates to dairy farmers residing either within or without the borough who supplied milk, cream, and butter to the inhabitants of Plymouth and who were willing to have their farms inspected. A list of dairy farmers to whom certificates shall have been granted will be published for the information of the residents of Plymouth every three months. This seems a wise decision of the council, for the recent typhoid fever outbreak at Plymouth was traced to contaminated milk. 88 cases occurred, 11 of which terminated fatally.

ST. MARY'S HOSPITAL.

TWO CASES OF "INTERSCAPULO-THORACIC" AMPUTATION FOR SARCOMA OF THE SHOULDER.

(Under the care of Mr. H. W. PAGE.)

THE chief value of Berger's method of complete removal of the upper extremity with the scapula consists in the early ligature of the subclavian artery, by which the loss of blood is minimised, and therefore the amount of collapse resulting from the operation is greatly reduced. For to collapse and to sepsis must be attributed the very heavy mortality which formerly followed attempts to remove the scapula with the arm, and of these two causes the collapse was probably the more potent. The mortality of interscapulo-thoracic amputation is not very great; Berger[1] has collected 46 cases in which the operation was performed for malignant disease of the upper end of the humerus, and only two of the patients died in consequence of the operation, a mortality of less than 5 per cent.

These two cases were in the hospital about the same time and had so many points of resemblance that they may be fitly recorded together.

CASE 1.—A man, aged 40 years, was admitted into St. Mary's Hospital on Dec. 11th, 1899. Over the outer end of the spine of the right scapula was a soft fluctuant swelling of the size of a small orange. It was painful and tender and the skin was much inflamed. The history was one of indefinite pain in the region of the shoulder for something like two years with a small swelling, which had latterly increased in size, for the past four months. Only recently had it become red and tender. In early life he had had an attack of acute rheumatism, and rheumatic pains had troubled him from time to time since, so that the diagnosis with which he came to the hospital from the medical man who sent him—viz., of inflamed bursal cyst connected with the joint—seemed entirely reasonable. To this at first Mr. Page inclined, but it was an ominous fact that the edge of the scapular spine was at one point deficient as if from erosive destruction. It was thought, moreover, that a tuberculous element might possibly be present in the inflammation, the patient's father having died from phthisis. On Dec. 12th the tumour was laid open by free incision and there was evacuated from a cavity with distinct wall or capsule between the trapezius and supra-spinatus muscles a soft, friable, exsanguine substance, pale in colour, the nature of which it was impossible to determine by naked-eye appearances. Some thought it looked like degenerating tuberculous granulation tissue, others that it was unquestionably sarcoma. In favour of the latter view was the destruction of the bone, but against it was the singular absence of bleeding at the operation. The wound was closed and quickly healed, but the microscope having revealed a round-cell sarcoma the necessity for early amputation was submitted to the patient. He declined any interference before Christmas and returned on Jan. 8th, 1900, with a condition of things much altered for the worse. A few days after leaving the hospital on Dec 23rd he had noticed a small lump at the site of the operation scar, and this had steadily increased so that there was now a definite tumour over the spine of the scapula measuring two and a half inches in the vertical by three and a half in the transverse direction. No glandular enlargement was to be found. Further delay was out of the question, and accordingly on Jan. 9th, with the help of his colleague, Mr. A. J. Pepper, Mr. Page removed the whole upper extremity by the method of Paul Berger. The upward extension of the growth involved the necessity of prolonging the incision over the trapezius, but with this exception the operation followed the lines laid down by Berger. There had been no difficulty in securing the subclavian vessels after resection of an inch of the centre of the clavicle and the remainder of the operation was free from hæmorrhage. Towards the close it was deemed advisable to give a subcutaneous injection of strychnine and brandy by the rectum, but the patient really bore the operation wonderfully well and neither then nor afterwards was there any degree of shock sufficient to excite alarm. For several hours he suffered intense pain from the divided nerves and it was imperative to give him morphine. The wound healed by first intention and the temperature was throughout normal. As regards the operation this may further be said, that a considerable portion of the trapezius muscle was removed and likewise every particle of adjoining fascia. Very careful inspection, moreover, was made of all the exposed tissues and there was no suspicion of any growth having been left behind. Nevertheless, the poor fellow was not long free from trouble. As early as Jan. 24th there was a suspicion of one or two small nodules being present in the quondam supra-clavicular fossa, and accordingly as much of the original wound was laid open as to enable examination of the divided trapezius and neighbouring parts to be made. One small lymphatic gland was taken out, some more of the cervical fascia, and a further portion of the trapezius muscle. Again the wound healed well and the patient left the hospital on Feb. 5th, in himself well and free from any indication of local recurrence. One thing, however, had not been liked about him, and that was that he had been suffering a good deal of pain in the left hip. He himself thought that it might be due to the constrained posture of lying on his left side so long in bed, and it was hoped that it might disappear when he began to move about again. Unhappily, it continued to increase and presently he was lame. He was seen from time to time and nothing was to be felt until March 30th, when he returned to the hospital and showed a distinct bony swelling below and in front of the great trochanter. There could be no question what it was and that surgical intervention was impossible. Now also were found two small nodules at the site of the operation, but these also it was resolved not to touch in presence of the secondary extension to other parts. He therefore left the hospital on April 4th and the next heard of him was that on the 13th his leg had given way and broken near the hip. Further recurrences took place at the right shoulder and "affected," so ran a letter about him, "both his head and his side lower down." After great suffering he died at home on May 19th.

CASE 2.—A pale, delicate-looking country girl, aged 19 years, was admitted into St. Mary's Hospital on March 3rd, 1900, with a tumour on the right shoulder. She had had rheumatic fever rather more than a year before and soon afterwards had noticed a small slightly painful lump on the shoulder. At first it had grown slowly, but during the last four months more rapidly. Over the apex of the shoulder, occupying the region of the supra-spinatus muscle, was a distinct tumour, of the size of a large hen's egg, giving a sense of deep-seated fluctuation and feeling much like a distended bursa. The skin over it was unaltered. The gravest fears were felt that the case was one of sarcoma, although the history suggested the possibility of an enlargement of one of the bursæ in connexion with her attack of rheumatic fever. On March 6th an exploratory operation was undertaken, at first with a needle and then by free incision through skin and muscle down to the site of the tumour. Blood alone escaped in considerable quantity and no new growth was actually seen, the blood presumably obscuring the tissues. The wound was closed, but because of the continuous oozing of blood it was necessary to insert a drainage-tube, and when two days afterwards the dressings were changed it was obvious that there had been septic invasion. Oozing of blood continued, and when on March 19th she was again put under an anæsthetic for further examination, distinct masses of a grey jelly-like material were seen projecting into the wound. Portions of this were submitted to examination, the verdict of the microscope being "mixed-cell sarcoma." Day by day the gelatinous material protruded in larger volume from the wound and it was obvious that the sarcoma was now increasing by leaps and bounds. Consent for previous operations had been obtained with difficulty and that for amputation was not had before March 25th, when, Mr. Quarry Silcock kindly helping him, Mr. Page removed the whole upper extremity. The operation

[1] Revue de Chirurgie, 1898, 861.

was an exact counterpart of that on the first patient and calls for no special remark save that during it a small deep-seated abscess was opened and probably infected the wound area. Shock was considerable towards the end of the operation but the patient soon rallied after return to bed. For the reason already named healing was not as good as could be wished and stitches had to be taken out earlier than usual. Nevertheless, there was at no time any collection of pus and only the margins of the wound gave trouble. The temperature was normal on the seventh day. She was then up and about the ward, gaining strength daily, and all pain had practically ceased. Suspicion of local recurrence on April 24th led to a further exploration, and a tiny nodule of growth, together with much thickened fascial structures, was taken from the divided edge of the trapezius and the whole upper part of the wound area was freely scraped so as to impart to it a healthier tone. Thereafter healing was more kindly, so that when she left the hospital on May 30th she might be pronounced quite well. Certainly there was at that time no sign of local recurrence, but a letter from her father in mid-December caused grave doubts on this point and the patient was urged to show herself at the hospital. At last, after much persuasion and entreaty, she consented to appear at the end of January of this year, but then only after definite promise that there should be no operation. A fluctuant subcutaneous lump of the size of a Tangerine orange was found over the right side of the spine at the level of the second, third, and fourth dorsal vertebræ, and this, it was urged, should be immediately removed, for careful examination failed to discover any other indication of recurrence either locally or in the internal organs. In herself the patient seemed wonderfully well, but there was a good deal of nervous hyperæsthesia over the whole shoulder region although no bulbous nerve ends could be felt. Accordingly she returned to the hospital and on Feb. 1st the tumour on the back was freely removed. It consisted of soft sarcomatous structure and one large cyst. There had been no invasion of muscular structures. From this operation she is now (Feb. 19th) on the road to early recovery, with some prospect, how faint cannot be known, that she may continue well.

Remarks by MR. PAGE.—I have thought these cases worthy of publication, not because there is anything specially new in them, but to emphasise my agreement with Dr. Russell S. Fowler of New York, who in an exhaustive paper in the *Annals of Surgery* for January and February, 1900, urges that all cases ought to be recorded. The first case exemplified in a remarkable degree some of the peculiarities of sarcoma—its insidious origin, its early quietude and slow rate of growth, its sudden outburst of extreme malignancy, and the difficulty of its diagnosis. More deceptive indications could hardly have been found than the duration of the swelling and the strange simulation of an abscess. Then, moreover, the surgical interference with the tumour seemed to determine, as has so often been noted, a fresh malignancy of singular violence, so that one would almost think that sarcoma in some of its forms is of all new growths the most malignant. One cannot help feeling that, after all, perhaps the man had better not have been subjected to operation, and it may well be doubted whether his life was prolonged by a single day. Wide dissemination of sarcoma soon followed the major operation, and as general tuberculosis is known to follow operations on local tuberculous diseases, so perchance it may be that the spread of sarcoma is likewise determined. The second case was clearly the less malignant of the two and there is no evidence that operation was in any way answerable for spread of the disease, even though the wound was septic; and here it seems justifiable to assume that removal of the extremity has secured both freedom from suffering and prolongation of life.

Serious shock was not pronounced in either case, attributable to a large extent, of course, to preliminary ligation of vessels and the avoidance of loss of blood. I do not doubt that it is a wise course to pursue in all cases in which the position of the growth, or other reason, does not render it impossible. In both cases it was perfectly easy to secure the subclavian vessels, while the operations as a whole were singularly free from those difficulties which may beset the surgeon in the removal of huge tumours, chondromata, and the like, which have been from time to time recorded and successful operations on which may be rightly regarded as veritable triumphs in surgery.

My thanks are due to my house surgeon, Mr. A. G. Wilson, for invaluable help in the treatment of these cases.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.

A SUCCESSFUL CASE OF GASTROTOMY FOR IMPACTED FOREIGN BODY IN THE ŒSOPHAGUS.

(Under the care of Mr. FLAVELL EDMUNDS.)

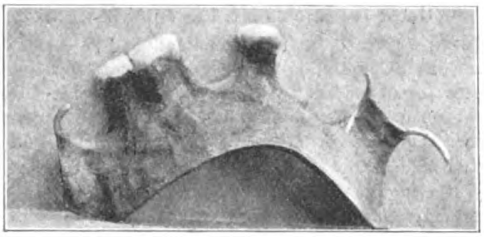
WHEN a foreign body is impacted in the lower portion of the œsophagus and cannot be displaced by the use of bougies three courses are open to the surgeon. He may, firstly, open the œsophagus in the neck and endeavour to remove the foreign body by forceps; this is the oldest method, and is not unlikely to prove successful unless the body is situated very low down. The second method is to perform an intra-mediastinal œsophagotomy; this is an operation extremely difficult and dangerous in itself, and it has, so far as we are aware, never been successful. E. Forgue [1] has described a case in which he attempted to perform this operation for an impacted coin, but he was obliged to desist on account of temporary cessation of breathing, and a fortnight later he was able to remove the coin through the mouth by means of a coin-catcher. In the third method, which is especially suitable when the foreign body is impacted near the cardia, a gastrotomy gives the surgeon access to the lower part of the œsophagus, whence the impacted body is removed by means of a finger or forceps. In a case recorded by Mr. D. Wallace [2] of Edinburgh an œsophagotomy was first performed for the removal of an impacted tooth-plate, but the forceps introduced could not dislodge it, so a gastrotomy was tried and the plate was successfully removed by means of a pair of forceps. The diagnosis in such cases as these can be much facilitated by skiagrams. Mr. Flavell Edmunds is to be congratulated on the successful issue of his interesting case.

A man, aged 45 years, on April 10th, 1900, went to sleep as usual without removing his plate of false teeth (consisting of three teeth with three hooks), but awoke about midnight feeling suffocated. His wife fetched him a drink which he swallowed and immediately felt a certain amount of relief in his dyspnœa, the plate evidently passing from the pharynx into the gullet. He was admitted into the Chesterfield and North Derbyshire Hospital early in the morning of the 11th feeling fairly comfortable and having little pain. Dr. A. G. Naylor, the house surgeon, attempted to remove the foreign body by means of a horse-hair probang but was unsuccessful, although on the first occasion the probang was felt to catch the plate. Mr. Edmunds saw the patient later in the day and passed a probang into the stomach without meeting with any obstruction and a further attempt later in the day met with no success. At this time it was thought that the plate had passed into the stomach. On the following day, however, the man suffered acute paroxysms of pain referred to the epigastric region with excessive tenderness over that area, but no vomiting occurred; it pointed to the conclusion that the plate was impacted at the cardiac orifice of the stomach. After a consultation with Mr. W. S. Symes and Dr. A. Green Mr. Edmunds decided to attempt to remove the foreign body through an opening in the stomach. Half an ounce of castor oil was given that night and an enema next morning, and just before the operation the stomach was well washed out with boric solution. On passing the tube for this purpose Dr. Naylor distinctly felt an obstruction before the tube entered the stomach.

An oblique incision two and a half inches long was made about one inch below the costal border to the left of the middle line. The stomach was found without difficulty and was held up into the wound by two silkworm-gut sutures passed through the serous and muscular coats only. Having packed it well round with sponges to prevent any fouling of the peritoneum, Mr. Edmunds made an incision through the wall of the stomach, transversely to its long axis, sufficiently large to admit the finger, but no trace of the plate could be felt in the stomach by finger or probe. The opening in the stomach wall was enlarged to about four inches, sufficient to admit the hand, which was inserted, and on passing the index finger into the œsophagus one of the hooks of the plate could be felt about two inches above the cardiac orifice. The plate was firmly fixed by means of two of the hooks to the œsophageal wall, but manipulation with long-curved forceps passed along the finger released it and it

[1] XIIe. Congrès de Chirurgie, Paris, 1898, p. 220.
[2] THE LANCET, March 24th, 1894, p. 734.

was removed through the stomach. The opening in the stomach was closed by a long continuous suture of fine silk for the mucous membrane alone, and the serous and muscular coats were brought into apposition by means of



The plate, showing the three teeth and three hooks.

between 30 and 40 Lembert's sutures also of fine silk. The parietal incision was closed by means of silkworm-gut sutures through the whole thickness of the wall.

For three days following the operation no food whatever was given by the mouth, thirst, which was a very troublesome symptom, being allayed by means of ice. The patient's strength was maintained by nutrient enemata which were continued for six days. Hypodermic injections of morphia were needed to procure sleep. On the fourth day after the operation half an ounce of peptonised milk was given hourly by the mouth and on the following day (April 17th) one ounce of peptonised milk and half an ounce of bovril were given alternately every two hours. On the 30th (17 days after the operation) the patient was taking middle diet consisting of minced meat with bread-and-butter, &c., and during the following week he was taking ordinary meat diet. The temperature for the first 10 days alternated between 99° and 100° F. and after that fell to and remained normal. The wound was first dressed on the sixth day and healed by first intention save for two small sutural abscesses which caused no trouble.

Remarks by Mr. EDMUNDS.—The above case seems to be worthy of record as, according to Mr. Treves's recent edition of "Operative Surgery," in the only two similar cases published the operation was performed by American surgeons (Dr. Bull of New York and Dr. Richardson of Harvard) in 1886 and 1887. The remarkable feature of the present case to me is that subsequently to the operation no pain whatsoever was complained of, either gastric or peritoneal, and the patient was entirely free from vomiting or any dyspeptic symptom whatever, and seven weeks after the operation he was following his occupation and felt in perfect health. The success of the operation was largely due to the constant attention of Dr. Naylor and to his efficient nursing staff.

PATHOLOGICAL SOCIETY OF LONDON.

Condition of the Renal Arterioles in Chronic Bright's Disease.—Toxins of the Pneumococcus.—Congenital Malformation of the Vesical Orifice of One Ureter.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 19th, Professor W. WATSON CHEYNE, the President, being in the chair.

Dr. W. P. HERRINGHAM read a paper on the Condition of the Renal Arterioles in Chronic Bright's Disease. After recapitulating the descriptions given by various authors he suggested that their extreme discrepancy arose from the want of a standard of health and of accurate numerical measurement in disease. He had endeavoured to supply these defects. The changes described were periarteritis, hypertrophy of the muscular coat, and endarteritis. The existence of the first two, at any rate, was by many authors denied. He himself had found it impossible to form any standard of the adventitia in health, and in disease he had found it to vary, not with the condition of the other arterial coats, but with that of the general interstitial tissue of the cortex. He held that it should be considered as a part of this rather than as a coat of the artery, and could not support the use of the term "periarteritis" as a separate condition. For the middle coat he used two measurements, the first transverse, by which in an artery cut transversely the relation of walls to lumen and the thickness of the various coats was determined; the second longitudinal, by which in an artery cut along its long axis the nuclei of the muscular coat could be examined and counted. Some test of the condition of the muscular coat was required, and he considered the number of nuclei present to be less liable to error than other criteria. When a set of standards drawn from six healthy kidneys were compared with a series of 34 cases of various forms of Bright's disease no instance occurred in the latter of true hypertrophy or of hyperplasia of the muscular tissue; but, on the other hand, whenever change occurred it was in the direction of thinning of this coat and diminution of its nuclei. Numerical tables were shown to illustrate this point. This was the case, not only when the disease was advanced, but even when it was in so early a stage as to be unrecognisable by the naked-eye. Fibrosis of the media was not uncommon in these arteries. Changes in the intima were also very common. He found the descriptions of endarteritis given in text-books faulty, since they omitted to notice the increase of elastic tissue which took place in the larger arterioles. He showed photographs of the concentric elastic rings found in these cases and argued that the specimens showed the earliest stage to be a swelling of the elastica with subsequent splitting into layers between which cells derived from the original membrane lay. Hyaline swelling appeared to be the form of endarteritis proper to the smaller arterioles, and he considered this condition to be probably the same process in some way varied by the size of the vessels. It always occurred in these cases along with fibro-elastic endarteritis in the larger arterioles. Besides these two forms he described a third, in which in the larger arterioles a cellular increase, probably formed from the endothelium, though circular in character, was found inside the ordinary fibro-elastic form. The cases in which this occurred showed some evidence, though not conclusive, of syphilis. With regard to the views (1) that Bright's disease was caused by endarteritis and (2) that arterial disease was the result of chronic inflammation of the surrounding renal tissue, he thought that each was probably true of some cases; but that the consequence was not in either case necessary he proved (1) by bringing forward two cases in which marked disease existed in the arteries though the renal tissue was not affected, and (2) by calling to mind the many cases of Bright's disease in young people which showed no arterial change. He thought that for the majority of patients the two diseases were separate and almost independent. The chief factor in the production of arterial disease appeared to be the age of the patient. No connexion could be traced between the degree of arterial and the degree or variety of renal disease. Looking upon arterial sclerosis as an almost universal form of degeneration he held that where Bright's disease was connected with it it was rather as a predisposing cause from its effect upon the general nutrition than as a direct excitant by mechanical obstruction or chemical irritation of the vessels. He disbelieved the theory which referred the high tension pulse to increased obstruction in the peripheral vessels and looked upon it as the effect of disease in the larger arteries by which the function proper to these, that of elastic reservoirs, was perforce transferred to arteries of smaller size.—Dr. J. ROSE BRADFORD agreed with Dr. Herringham as to the fundamental points. It was impossible to correlate the arterial and the parenchymatous changes. With regard to high arterial tension it was not necessarily related to local arterial changes in the kidneys, nor was it settled that the cardiac hypertrophy was attributable to increased resistance. Something might still be said in favour of the old view that the cardiac hypertrophy was of a toxic nature and the renal were secondary to the cardiac changes.—Dr. A. G. AULD agreed with Dr. Herringham that the elastic tissue of the arteries in chronic nephritis underwent a process of splitting. Similar changes had been observed in Bowman's capsule.—Mr. S. G. SHATTOCK asked whether any precautions had been taken to ensure that the arteries examined had been exposed to equal pressure.—Dr. HERRINGHAM, in reply, had found that it was safer to rely on obtaining an average by making a great number of observations upon arteries removed from

the body 24 hours after death than by making injections at given pressures. One objection to the latter proceeding was that the normal average blood-pressure in the renal arteries was an unknown quantity.

Dr. AULD read a paper on Additional Remarks on the Toxins of the Pneumococcus. Experiments he had described on a former occasion were to the effect that infection of the pneumococcus toxins, instead of conferring any active immunity, only served to render the animal more sensitive to the toxins themselves and also to the organism. Additional experiments had shown that the sensitiveness lasted a long time, at least for eight months. Such a phenomenon as supersensitiveness was met with under many conditions, but in the experiments described it seemed constant. The work of Issaeff had thrown light on the subject. He found that rabbits made completely refractory to the pneumococcus itself nevertheless remained highly sensitive to its toxins, much more so than normal rabbits. Hence he concluded that no antitoxin was formed by the pneumococcus. Issaeff's results were in entire harmony with those of Dr. Auld—that was to say, in both cases no antitoxin was present. In Dr. Auld's experiments the toxins were alone injected, and the only anti-bodies which they could call forth were the antitoxins. As they failed to do so the subsequent inoculation of the toxins themselves or of the virus must necessarily be ineffective. Not only so, but such toxins could only be a source of injury and so the increased sensitiveness. They had to look, therefore, in immunity from the pneumococcus to anti-bodies produced by the bacteria themselves, or, according to the side chain theory of Ehrlich, the immunising serum produced by the bacteria contained a body which had two haptophore groups, one which combined with the bacterial cell and the other, or grappling arm, that which attached to the ferment which dissolved the cell. The simple albumoses were useless in immunising against pneumonia. The questions arose, Why was no antitoxin produced? and What was the immediate cause of the sensitiveness? These phenomena were mutually dependent. There must be an excessive accumulation of side chains in the susceptible cells and the failure to cast them off into the blood as antitoxins. Such overloading of the cells would tend to injure them and render them more susceptible. Dr. Auld adduced considerations as to why the antitoxins were not thrown off. Finally, two facts might be explained. One related to the frequency of recurrence of pneumonia; the immunity produced by the "anti-bodies" was short, while the action of the toxins was long. This explained the phenomenon. The other question referred to the failure of serum treatment of pneumonia in man. This was to be accounted for by the fact that the "anti-bodies" in the immunising sera were only capable of exercising their immunising properties on individuals of the same species. Hence the curative serum would be got from immune human beings or possibly from apes.

Mr. RAYMOND JOHNSON exhibited the Genito-Urinary Organs of a Female Infant in which there was a very Unusual Malformation of the Vesical Orifice of the Left Ureter. From the normal position of the latter a raised column attached to the wall of the bladder ran forwards and ended in a bulbous enlargement which protruded through the dilated urethra, forming a closed cyst which emptied spontaneously on the sixth day after birth. In addition to this malformation the left kidney was imperfectly divided into two portions, each having a separate ureter, the two ureters uniting at a point just above the bladder. The right kidney and its ureter were normally formed, but the latter was dilated. The genital organs and the large intestine were normal. The infant from which the specimen was obtained had died on the thirteenth day, evidently as the result of urinary infection. Before its rupture the distended ureteral orifice had projected through the urethra and between the labia as a small egg-shaped tumour. A similar malformation had been previously described and must be referred to an early error in development. It was probably dependent upon a failure in the natural separation which occurs between the lower extremities of the ureter and the Wolffian duct. The ureter was thus drawn downwards during the formation of the septum, dividing the urogenital sinus so that it came to open in the floor of the urethra.—Mr. DOUGLAS DREW referred to a case in which a child lived three weeks with a similar condition of the ureters.—Dr. A. F. VOELCKER referred to an example of the condition in the museum of the Middlesex Hospital.—Mr. SHATTOCK agreed with Mr. Johnson as to the origin of the defect. He (Mr. Shattock) had termed the condition a reversion to a reptilian type of structure.

Mr. DREW showed a specimen comprising the Kidneys, Ureters, and Bladder removed from the body of a woman, aged 39 years. Above the middle of the left ureter a rather large calculus was impacted and the part of the ureter above it was stenosed. The left kidney was hydronephrotic and contained a large pear-shaped stone. The patient died suddenly from uræmia and was admitted with hæmaturia of ten days' duration.

Mr. A. CORRIE KEEP showed a Hydronephrotic Right Kidney which contained 25 ounces of thick pus and some blood-clot and a small uric acid stone. The patient had had no rise of temperature and very little pain.

LIVERPOOL MEDICAL INSTITUTION.

Report on the Outbreak of Arsenical Poisoning in Liverpool amongst Beer-drinkers.—Appendicitis.

THE tenth ordinary meeting of the session was held on Feb. 14th, Mr. EDGAR BROWNE, the President, being in the chair.

At an ordinary meeting of the institution held on Dec. 20th, 1900, a discussion took place on an Outbreak of Arsenical Poisoning amongst Beer-drinkers, and at the close of the meeting a sub-committee was formed to consider the matter and to report to the institution. This report was now made to the meeting. It re-established the fact that during the last six months a considerable increase of cases usually described as alcoholic neuritis had been observed by medical men in Liverpool. These had in the majority of cases been limited to the poorer classes, hence the best opportunity for observation had been in the union hospitals and general infirmaries. On careful inquiry into the histories of those attacked it had been found without exception that they had been in the habit of drinking beer, generally of a cheap quality, either in small quantities or to excess. The explanation of this sudden increase in the number of cases of neuritis and the presence of some unaccustomed symptoms was afforded on Nov. 22nd, 1900, by the discovery of Dr. E. S. Reynolds of Manchester that arsenic was present in the beer consumed by the patients. In Liverpool the matter was investigated by the medical officer of health, who caused samples of the suspected beer to be taken and subjected to analysis. The result of these analyses showed in a number of cases serious contamination with arsenic. Further investigation showed that the source of the arsenic was impure sulphuric acid which had been used in the manufacture of glucose and other sugars. These sugars were employed as brewer's substitutes in the manufacture of beer. The arsenical sulphuric acid was made from arsenical pyrites, whereas nothing but pure sulphur should be used in the preparation of acid which was destined to be employed in the preparation of food products. The analyses showed that in some samples as much as one and a half grains of arsenic were found to a gallon of beer—a very serious and dangerous contamination. The number of persons attacked had been considerable, certainly several hundreds, and of this number many died. A table of 116 cases occurring in Liverpool and Birkenhead which admitted of easy verification had been drawn up and were appended to the report. Of the 116 cases nine persons died and five were inquest cases. The committee were aware of a large number of cases occurring in other institutions and in private practice. The withdrawal and destruction of the contaminated beers in Liverpool was followed almost at once by a great diminution of cases of neuritis and it was satisfactory to record that the epidemic had been overcome. The possibility of an article of such general consumption as beer being contaminated by a deadly poison such as arsenic had caused widespread alarm to the community and to the medical profession, and the committee felt that it was necessary that some prompt steps should be taken by the legislature to obviate any such serious dangers to the health of the public in future as, considering the prevalence of chemical methods of manufacture deleterious substances, might at any time be introduced. Upon the facts as set before them the committee unanimously made the following recommendations:—

(1) That means be taken to secure purity of beer; (2) that a strict supervision of the materials selected for use in the manufacture of beer was necessary; and (3) that all beers should be labeled by the brewers showing their exact composition.

Mr. F. T. PAUL and Mr. R. W. MURRAY introduced a discussion on Appendicitis. Mr. Paul's paper was chiefly concerned with treatment especially as regards the value of early operation. He endeavoured to show from past clinical and post-mortem records that the mortality in acute attacks never had been high, probably not more than 6 or 7 per cent., the deaths then, as now, being mostly due to septic peritonitis. Early operation as a general rule of treatment could only be accepted if it lessened the direct mortality due to acute attacks. The prospect of a recurrence was no argument in favour of it, as this could be treated with much less risk after convalescence. Nor should the fear of septic peritonitis encourage hasty operations. This dangerous complication was usually established from the first, whilst many surgeons operated because there was a lump and they were afraid it would burst into the peritoneum. A lump was not a source of danger, but an evidence that a danger had been averted, and even although an abscess might form the peritoneal cavity was the last place into which it was likely to discharge. So far as he could judge the mortality from early operation was much greater than the mortality from the disease as it occurred in England. Mr. Paul recommended operation at once in septic peritonitis or in abscess as soon as a definite collection of pus was recognised and in attacks which did not clear up—relapsing appendicitis. Otherwise the operation should always be postponed till after convalescence, when it might be undertaken in children after a first attack, as the mortality was almost *nil*, but in adults it should not be undertaken unless a second attack supervened. He recommended that an ordinary acute attack of appendicitis should be treated by rest, local warmth, starvation, and opium with discretion, and considered purgatives and milk diet as responsible for many disasters. Finally, he referred to various details which he believed contributed to the success of the operation. His mortality in operations undertaken during a quiet interval was at present under 2 per cent. Mr. Murray in his paper, after reviewing the evolution of the gastro-intestinal tract, said that the teaching of comparative anatomy pointed to the vermiform appendix being the remnant of a greater cæcum. Though many of the lower animals possessed a long and pointed cæcum they seldom suffered from an affection at all akin to appendicitis, the probable explanation being that in them it served a definite physiological purpose. The greater frequency of appendicitis amongst civilised nations was no doubt due to their more complex diet. The anatomy and histology of the appendix was mentioned and the probable sequence of pathological events which led up to, and terminated in, an attack of appendicitis was explained. The clinical symptoms which corresponded to these pathological changes were commented upon, especially those symptoms which pointed to commencing bacterial invasion of the general peritoneum, for in such cases early operative interference was urgently called for.

Sir WILLIAM M. BANKS considered that many of the cases that were called mild appendicitis nowadays were really cases of typhlitis and perityphlitis; these were of the mildest nature and recovery without operation was almost invariable. Appendicitis proper he considered in three stages: (1) pre-suppurative; (2) suppurative; and (3) quiescent. 1. The pre-suppurative stage was one from which recovery might be expected in many cases without operation, the treatment being starvation with fomentation of the flank. He deprecated the use of opium as a routine treatment, as it was apt to mask the symptoms of the disease and produce symptoms of its own. The signs of danger were a slight rise of temperature, a rapid pulse, an increase in the amount of swelling, and drenching sweats. 2. As soon as the suppurative stage had been diagnosed the pus should be evacuated, when the appendix was practically destroyed, and such patients had no return of appendical trouble. 3 In the quiescent stage a valuable advance had been made by the removal of the appendix in cases of recurring appendicitis. He would let the patient have three attacks before removing the appendix, because the second attack was often a very mild one and only a recrudesence of the original one which had not quite cleared away.

Mr. W. THELWALL THOMAS considered operative interference necessary if in 48 hours the symptoms and signs did not decrease. Well-defined induration in the iliac fossa persisting after that time indicated the presence of pus and being separated from the general peritoneal cavity by recent soft adhesions tended to burst in that direction. He deprecated the routine use of opium in acute abdominal affections and found that the application of collodion and belladonna to the iliac fossa under hot fomentations soothed pain best; but if after 24 hours these applications increased the pain suppuration was probably present. In relapsing cases operation was always necessary and was certainly indicated in recurrent cases if after two or three attacks the patient was incapacitated from exercise or if the attacks became more severe. In such cases pathological changes were always found in the excised appendage.

Dr. MACFIE CAMPBELL, considering the subject from the general practitioners' side, said that he always gave opium or morphia, as the immediate relief of pain was necessary and helped towards a more accurate diagnosis. His experience of its use was most favourable. Poulticing was valuable in relieving pain and as a diagnostic agent between congestion and suppuration. Operation was advisable in recurring cases.

Dr. GEORGE G. HAMILTON did not consider the temperature an important sign, for the abdomen might be full of pus and the intestines all matted together after a perforated appendix or typhoid ulcer and yet there might be little rise of temperature. He had seen appendices five and six inches long causing obstruction to the ascending colon and rectum respectively.

Dr. ARTHUR EVANS referred to a very acute case of appendicitis in a child who was operated upon within half an hour of the appearance of first symptoms and the appendix was found to be bulbous and to contain pus. He also related a case of gunshot wound of the abdomen (which he had seen in South Africa) where the signs and symptoms produced were those of perforative appendicitis, and it was found that the appendix had been wounded by the bullet.

Dr. F. S. PITT-TAYLOR thought starvation a bad preparation for a serious operation. He emphasised the fact that in raw eggs well beaten up in water they had a perfect food, always liquid and capable of almost complete absorption.

Dr. WILLIAM CARTER and Mr. RUSHTON PARKER also spoke and Mr. PAUL and Mr. MURRAY replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Plague.—Proteids in the Urine.—Exhibition of Drawings and Specimens.

A PATHOLOGICAL meeting of the above society was held on Feb. 15th, Dr. GORDON BLACK, the President, being in the chair. Before proceeding to the business of the evening the PRESIDENT referred in a few well-chosen words to the death of Her late Majesty Queen Victoria.

Dr. E. F. TREVELYAN read a paper based upon a bacteriological investigation of the recent cases of Pneumonic Plague in Hull. The morphological and cultural peculiarities of the bacillus pestis were first described and illustrated by specimens, preparations, and drawings. In discussing the bacteriological diagnosis Dr. Trevelyan thought that if the lung contained large numbers of a micro-organism with the morphological and staining peculiarities of the plague bacillus a positive diagnosis should certainly be given without awaiting confirmation by cultivation and experiment. This had been done in the first two of the Hull cases. As regards the sputum, a careful and often-repeated examination had been made in four of the cases, the results being controlled by inoculation experiments. None of the sputum received from these cases presented in cover-glass preparation a pure culture of the plague bacillus. In fact, there were so many micro-organisms present that the examination was often rendered very difficult. Cultivation of the sputum in broth at 22° C. in two instances had proved of no real service. The sputum received was nearly always viscid and more or less rusty in appearance. Blood had been examined from three cases and the plague bacillus was readily found by cover-glass preparation in two cases and by cultivation in all the cases. The examination of the blood, although of distinct service in one case, is usually rendered of less value from the diagnostic point of view from the fact that the bacilli are not likely to be found until late in the disease. In the confirmatory inoculation experiments more

satisfactory results had been obtained with guinea-pigs than with white rats. In conclusion, Dr. Trevelyan thought that the danger of investigating plague material could be overstated, although, of course, careful precautions must be taken, especially in keeping the inoculated animals, in not directly handling them or their tissues, in immediately sterilising all instruments, &c., used, and in cremating the carcasses.—Dr. POWELL WHITE and Mr. CAMMIDGE took part in the discussion, and Dr. TREVELYAN replied.

Mr. P. J. CAMMIDGE read a paper on the Significance of some forms of Proteid found in the Urine in Bright's Disease. After briefly referring to the methods of separating and estimating serum, albumin, and globulin in the urine Mr. Cammidge showed, by means of the lantern, a number of charts illustrating the daily variations in total and percentage proteid excretion, also the relation between the albumin and globulin passed in various forms of nephritis, including the albuminuria of pregnancy and eclampsia. Reference was made to the influence of paracentesis, to the induction of premature labour, and to the rise of temperature on the excretion of these substances. Most of the cases had been under observation for several weeks, some for two or three months, and in all a daily examination of the urine, including proteid estimations, had been made. After considering the cases in detail Mr. Cammidge stated that he believed the percentage, or better the total amount, of serum globulin present in the urine in a case of nephritis was the surest indication of the severity of the disease of the kidney. In estimating the globulin, however, it was important to eliminate the influence of mucus (nucleo-proteid) on the result as far as possible by the use of the catheter in women, especially those who were pregnant, and the lack of this precaution might account for the generally accepted statement that the globulin exceeded the albumin in amount in eclampsia—a statement with which he did not agree.—A discussion followed in which the PRESIDENT, Dr. LONG, Dr. A. G. BARBS, Dr. T. W. GRIFFITH, and Dr. J. B. HELLIER took part, and Mr. CAMMIDGE replied.

Dr. J. KERR (Bradford) showed a number of drawings from cases of Vascular Obstruction in the Retina. In four cases of embolism of the central artery small macular twigs had escaped and a minute, nearly central, portion of the field persisted. In one of these cases streaming movement of the blood in the veins was seen for nearly a week from the onset, and in another broken-up pulsating venous columns were noticed for several days.

The following specimens were shown:—

Mr. CAMMIDGE: (1) A Colloid Carcinoma of the Omentum; (2) a Carcinoma of the Hepatic Flexure of the Colon; and (3) (with Dr. A. L. WHITEHEAD) Tuberculous Iritis, showing Tubercle Bacilli.

Dr. PRIESTLEY LEECH (Halifax): (1) A large Chronic Ulcer of the Stomach; and (2) a New Growth and Cirrhosis (?) of the Liver.

Mr. SECKER WALKER: A specimen of Intra-ocular Hæmorrhage after Cataract Extraction.

Dr. HELLIER: Specimens from cases of Carcinoma Uteri treated by Hysterectomy.

Mr. W. H. BROWN: Myoma Uteri removed by Abdominal Hysterectomy.

Mr. WALTER THOMPSON: Fibro-myoma of the Uterus (undergoing sarcomatous degeneration?).

Dr. GRIFFITH: (1) Embolism of the Cerebral Arteries; and (2) the Heart and Pancreas from a case of Diabetes Mellitus.

Dr. BRONNER (Bradford): Microscopic specimen of a small Sarcoma of the Upper Turbinated Bone, which caused Epistaxis for one and a half years (death).

Mr. H. J. ROPER and Mr. LAWFORD KNAGGS: Bladder and Kidneys from a case of Enlarged Prostate, showing enormous dilatation of one ureter and kidney.

Mr. LAWFORD KNAGGS: Malignant Disease of the Rectum (perforation of the cæcum).

Mr. B. G. A. MOYNIHAN: (1) (with Dr. W. H. M. TELLING) A Rectum with Fæcal Concretions in Appendices Epiploicæ, giving rise to inflammatory adhesions and obstruction of the small gut; (2) Keloid of the Breast; and (3) Cystic Disease of the Kidneys and the Liver.

Dr. E. WARD: (1) Epithelioma of the Soft Palate; and (2) Growth of the Jaw.

Mr. MAYO ROBSON: (1) Malignant Disease of the Cæcum (excised); and (2) Carcinoma of the Stomach (excised).

Dr. TREVELYAN and Mr. CAMMIDGE showed 40 specimens recently added to the School Museum, including amongst others: an Infarct of the Spleen with Aneurysm of the Splenic Artery; a large Compound Ganglion of the Wrist; Two Bronchial Cysts, one from the parotid region the other from the neck; a Lipoma of the Small Intestine causing intussusception; a Sarcoma of the Testis with Hydrocele; a Cystic Papillomatous Growth of the Left Ovary, the right having been removed six weeks before for a similar disease; a large Hydatid Cyst of the Kidney from a boy, aged six years; a Sarcoma of the Liver and Left Axillary Glands (the liver weighed 17 lb; no other growth was found); a large Fibroma of the Cervix Uteri from a woman, aged 23 years (the uterus appeared as a small knot on the summit of the growth); and a Cystic Omentum which microscopically proved to be a Lymphangioma.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 8th, Dr. F. F. Schacht, the President, being in the chair.—It was unanimously resolved—

That an address of sympathy and condolence, conveying the society's expression of loyalty and respect, be sent to His Most Excellent Majesty the King.

—Dr. Campbell Pope then read a paper on the Feeding of Infants in Health and Disease. He said that the problem as presented by nature was one of extreme simplicity, but advancing civilisation had added great complexity to it. In cases where artificial feeding was imperative he recommended the system of physiological feeding as advocated by Holt and Rotch in America and supported by Cautley, Pritchard, and others in this country. For the well-to-do the necessary modification of the milk to the varying standard of human milk at different periods was ably carried out by the Walker Gordon milk laboratories. For others in less favoured circumstances Pritchard's tables for home use supplied the necessary information. He then described milk prescriptions for the modification of milk in accordance with the various failures in digestion of fats, proteids, or carbohydrates, as evidenced by a critical examination of the stools. The prevention of rickets and scurvy was alluded to and special reference was made to virol as being useful from containing citrate of lime. After discussing the subjects of overfeeding and weaning Dr. Pope described the various pollutions which accrued to milk under present conditions in its transit from the cow's udder to the mouth of the infant and strongly advocated more method and simplicity. Most sanitary evils could be avoided by bottling at well-inspected farms and the universal adoption of the physiological method of feeding would introduce simplicity instead of complexity and confusion. He hoped the time would come when municipalities would see that nurse children under their supervision in homes, crèches, or institutions were afforded the benefit of properly modified pure milk.—Dr. Harry Campbell insisted upon the advisability of feeding children after weaning on hard, coarse foods needing prolonged mastication. He regarded the present plan of feeding children upon soft, pappy foods as most pernicious and as being the chief cause, from want of proper use of the masticatory apparatus, of dental caries and adenoids.—Mr. T. R. Atkinson said that he did not think that the want of hard food for children after weaning was the cause of caries of the teeth and adenoids.—Dr. Leonard Dobson said that feeding-bottles must be used in many cases, and he advocated the "Allenbury" as being the simplest and most easy to keep clean. He considered Dr Pope's tables and methods of preparing milk food admirable, but applicable to but a limited class. He was certain that the average nurse or mother of the middle classes could not be trusted to carry out daily accurate measurements of the quantities required and efficient sterilisation of the apparatus. Something simpler was required and he had found the Aylesbury Dairy Co.'s humanised milk to be a most satisfactory preparation. It was sterile, contained the right proportion of fats, proteids, and carbohydrates, and if considered too rich the cream, which always rose to the top of the bottle, could easily be reduced in quantity. If this was considered too expensive then he suggested the use of their sterilised milk, which was but little dearer than ordinary milk. If for various reasons it was necessary to use tinned milk, then he suggested that Nestlé's sterilised, unsweetened, condensed milk was the best. In all cases of diarrhœa and vomiting he stopped the use of milk altogether for two or three days and used a simple mixture of white of egg in boiled water, with the addition of a few drops of

meat-juice. He urged that infants when ill should be given plenty of plain boiled water to drink and not such large quantities of their usual food.—Dr. J. B. Ball said that he could not agree with Dr. Campbell that the want of hard food with infants was the cause of adenoids. He had repeatedly seen infants of from one to four months old with adenoids.—Dr. Langdon-Down said that he had carried out in his own family the recommendations described in Holt's work. He used Hawksley's apparatus for pasteurising the food.—Mr. W. Milner Burgess said that he used Aymard's steriliser with great success in the feeding of infants.—Dr. Twynam pointed out the value of citrates as preventing rickets, and he suggested that fresh orange juice or lemon juice should be given to the infant or to the nursing mother.

BOURNEMOUTH MEDICAL SOCIETY.—The members of this society have recently acquired rooms in the Shaftesbury-hall Chambers, 74, Old Christchurch-road, for their library and to hold their meetings in. The committee have incurred considerable expense in the ventilating and heating arrangements of the rooms, in installing the electric light, and in providing the necessary fittings and furniture. Nearly all the medical men practising in Bournemouth and its neighbourhood are members of this society. The library contains a large number of medical and surgical works of reference besides weekly and monthly periodicals. The members held their first monthly meeting in their new rooms on Feb. 13th, when there was a large attendance, Dr. Arthur Ransome, the President, being in the chair. The President said, before having the minutes read, that there were two things which he wished to allude to. The first and most important was the death of the Queen. It was not necessary for him to say anything about the illustrious example set by the late lamented Sovereign, he would simply quote the words of Vaughan:

> "She has now gone into the world of light
> And we alone sit lingering here;
> Her very memory is warm and bright,
> And our dull thoughts doth cheer."

The second thing which he wished to allude to was that that was the first meeting of the society in the new rooms. He thought that the society was to be congratulated on having acquired a fixed abode so that it was no longer a peripatetic body. He congratulated the members on the way in which they had responded to the appeal made to them for funds to meet the special expense involved in providing furniture and fittings, &c.—The minutes of the special and ordinary meetings held on Jan. 9th were read and signed.—Dr. Percy J. Duncan showed a child, aged 11 months, with an Inflammatory Swelling on the Left Buttock and a Nævus on the Right Buttock which was stated to be increasing and asked the opinion of the members in reference to the nævus, especially as to treatment.—The President brought before the society a communication as to the British Congress on Tuberculosis to be held in London in July, 1901. It was resolved "that the matter be referred to the committee to consider."—Dr. G. E. Crallan read a paper on Delirium in General Diseases. He said that delirium might be defined as a perversion or loss of control of the mental processes which might be manifested in speech or action. The characteristic of healthy mental processes was that they were in harmony with the actual sensory impressions of the present and with the memory of those of the past. In delirium this concord was lost and mental processes ceased to correspond to realities; firstly, there were false ideas—that was, "delusions"; secondly, sensory images arose without sensory impressions from without—that was, "hallucinations"; and thirdly, actual sensory impressions from without excited erroneous sensory images—that was, "illusions." The term "delirium" was usually confined to temporary mental derangements occurring in connexion with disease which was otherwise recognisable. A similar mental state occurring apart from such recognisable diseases was regarded as insanity. Delirium might be quiet or active. In quiet delirium there were delusions and hallucinations which dominated the patient's ideas. He often talked almost continuously in a low monotonous voice with the words imperfectly articulated—a condition termed "low muttering delirium." In active delirium the patient tried to act according to his erroneous and distorted ideas, such as getting out of bed, running about, smashing things, or trying to jump out of a window. He mentioned the diseases in which delirium occurred as a symptom, its etiology in these conditions, and its diagnosis and treatment, in the course of which he narrated some interesting cases.—The President congratulated Dr. Crallan on his excellent summary on this interesting subject and mentioned some cases which had occurred in his own practice.—Dr. Alderson, Dr. Vernon, Dr. Simmons, Mr. T. F. Gardner, and Dr. Hyla Greves took part in the discussion and Dr. Crallan replied.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 13th, Dr. A. T. Wilkinson, the President, being in the chair.—Dr. E. F. Trevelyan (Leeds) read a communication on Some Tumours of the Dura Mater. He first referred to the minute structure of the dura mater. Of three specimens of psammoma shown two originated from the falx cerebri and the remaining one from the dura mater over the Rolandic area. A fourth psammoma, of which sections only were shown, started from the meninges of the base. All these tumours were of small size with the exception of one of those which sprang from the falx. The other tumour growing from the falx was hard and contained much calcareous material, whereas the growth over the Rolandic area was quite soft. Both these tumours only contained well-formed fibrous tissue in addition to the psammoma bodies. The remaining two tumours belonged to the endotheliomata. Dr. Trevelyan thought it more useful to classify these growths according to the preponderating tissue present—e.g., psammo-fibroma, &c. The so-called psammoma bodies were not peculiar to tumour formation, for as far as the dura mater alone was concerned they had been found in pachymeningitis (Ribbert) and even in the normal dura mater (Ford Robertson). The microscopical sections seemed to favour the view that the concentric bodies originated from aggregated endothelial cells, but numerous rod-like and needle-shaped structures were also present. The large tumour was directly responsible for death, whereas the basal tumour was an accidental find at the necropsy. The patient with the psammo-fibroma over the Rolandic area fell downstairs probably in an attack of vertigo and sustained a fatal fracture of the base. The only symptoms present here during life were two or three attacks of fainting or vertigo during the last few weeks of life. Dr. Trevelyan referred to another case of a small fibro-sarcoma of the dura mater indenting the temporo-sphenoidal lobe in which death was sudden and no other lesion was found in the body. Of two specimens of osteoma of the dura mater the one showed several small growths on the outside of the dura mater, and the other, a simple growth, proved to consist of pure bone and presenting the shape of a limpet-shell. A specimen of Multiple Tuberculous Growths from the dura mater in the posterior fossa was also shown, as well as a Gummatous Growth of the Meninges over the arm-centre in which the pia-arachnoid appeared to pass beneath the growth.—Mr. Montgomery described a case of Growth of the Aryteno-epiglottic Fold.—Dr. J. H. Ray showed and described three specimens of Acute Intussusception. 1. Acute ileo-cæcal intussusception of at least five days' duration, presenting two rents in the intussuscipiens near the apex of the "tumour," which was four inches long, irreducible, and was excised during life from a male child, aged seven weeks, in whom end-to-end anastomosis was then carried out. Microscopic sections revealed submucous hæmorrhages, increase in number of goblet cells, and marked œdema of the circular muscular tissue. 2. A reduced ileo-cæcal intussusception of 24 hours' duration from a male child, aged seven months. The patient lived five days after operation and the bowels were moved four times. He eventually died from paralytic obstruction of the small bowel. In the caput cæci a submucous hæmorrhage was to be noted. 3. A reduced colocolic intussusception from a male child, aged four years, in whom symptoms had existed for at least 14 hours. The apex of intussusception was on the anterior surface of the transverse colon and still showed as an oval patch, one inch by half an inch of marked congestion and extravasation. The microscopic appearances were similar to those in the first of the three cases.—Dr. E. S. Yonge made a short communication on Simple Growths of the Tonsil.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 14th, Dr. E. Wearne Clarke, the President, being in the chair.—Mr. C. Atkin showed a patient upon whom he had operated for symptoms of Acute Intestinal Obstruction caused by pressure of a large

hydronephrosis. The right kidney, absent from its normal position, presented in the epigastric region, pressing forward the transverse colon and stomach. On scratching through the omentum a cyst of the size of a cocoa-nut was discovered and it was tapped. The patient, a youth, aged 19 years, though *in extremis*, recovered perfectly and six weeks later had had no signs of recurrence.—Dr. D. Burgess showed the following specimens: (1) the Organs from a case of Lardaceous Disease without apparent cause; and (2) Extensive Cerebral Softening due to Thrombosis of the Middle Cerebral Artery from a case of Senile Diabetes.—Mr. H. A. Mason (for Mr. A. J. Hall) showed two cases of Aortic Stenosis in young women and Extreme Clubbing of the Fingers in a case of Phthisis.—Mr. A. K. Gale and Mr. H. Hallam reads notes of eight cases of Peripheral Neuritis accompanied by Pigmentation of the Skin occurring among Beer-drinkers. The cases comprised six women and two men. In the majority the illness commenced with digestive disturbance, numbness, and sensations of "pins-and-needles" in the hands and feet, soon followed by loss of power in the arms and legs. They all presented the following physical signs: (1) varying degrees of peripheral neuritis up to complete loss of power; (2) brown pigmentation of the skin all over the body, most marked on the abdomen and chest, followed by desquamation; and (3) thick desquamation of the skin and redness of the palms of the hands and the soles of the feet. In all but one case, a known alcoholic, the mental condition was perfectly good. The beer—a light ale—taken by four of the patients was pronounced by the Derby county analyst to contain arsenic in dangerous quantity.—The President, Dr. Burgess, Dr. S. White, Dr. R. Gordon, Mr. E. Skinner, Mr. R. J. Pye-Smith, Mr. Atkin, Dr. F. H. Waddy, and Dr. J. Sorley joined in the discussion.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 7th, Dr. D. B. Lees, the President, being in the chair.—Dr. Inglis Parsons read a paper on Persistent Metrorrhagia, which is published in the present issue (p. 547).—The President suggested that some of these uterine hæmorrhages might be due to very small abrasions, as was sometimes the case in hæmorrhage from the stomach, and that others might be due to constitutional causes, such as increased arterial tension.—Dr. Davson remarked that he had listened with much attention to the paper read by Dr. Parsons. It had given him further insight into the treatment of menorrhagia which on several occasions had baffled all the ordinary treatments. It was presumable that those patients who did not yield to treatment within a given time did so only from persistency in treatment and the constant recumbent position. He had had cases where curetting had failed, and no doubt had he known of the electric treatment suggested and used by Dr. Parsons the patients would have made a speedy and successful recovery. He would certainly on the next opportunity give it a trial.—Dr. Inglis Parsons, in reply, said that any battery would do provided that it had sufficient output to give the necessary strength of current. By the use of the galvanometer they could give a fairly exact dose. With regard to the use of steam they had to wait to see if the result would be permanent. He would much prefer its use to electricity if the hæmorrhage could be stopped with one application. Some of his cases of fibro-myoma had now kept free from hæmorrhage for 10 years and he therefore felt that he could rely on electricity. Sclerosis of the uterine arteries would not explain the persistent menorrhagia in his cases because the patients were mostly women under 40 years of age. It was quite exceptional for sclerosis to occur before middle life.

NORTH-EAST LONDON CLINICAL SOCIETY.—A meeting of this society was held at Tottenham Hospital on Feb. 7th, Dr. E. Hooper May, the President, being in the chair.—Dr. Tresilian showed a case of Myopathic Paralysis and a case of Congenital Facial Diplegia.—Dr. S. E. Dore showed a boy, aged 15 years, with innumerable Subcutaneous Nodules, presenting microscopically a Fibrous Structure. The skin was markedly elastic and there was a tendency to subcutaneous hæmorrhages. The boy had also congenital heart disease. All his joints showed over-free mobility and he had an old-standing injury to the left elbow.—Mr. Douston showed a case of long-standing Fixation of the Mandible the result of rheumatoid arthritis.—Dr. R. Murray Leslie showed: (1) A case of Congenital Heart Disease; and (2) a Specimen of Malignant Disease of the Omentum and Gall-bladder removed post mortem from a woman who had been in the hospital suffering from Chylous Ascites.—Dr. Arthur Giles showed: (1) A Dermoid Cyst of the Ovary removed by Abdominal Section; and (2) a Uterus with several Fibroid Tumours removed by Abdominal Hysterectomy.—Dr. Chappell showed: (1) A Tumour of the Pons removed post mortem from a child (who had previously been shown to the society) who had presented unusual focal phenomena; and (2) an Œsophageal Growth with microscopical section showing it to be of a sarcomatous nature.—Mr. Carson showed a Scirrhus of the Pylorus removed by Pylorectomy and Gastro-duodenostomy by Kocher's method.—Dr. Meachen showed a microscopical specimen of Ringworm showing the large-spored fungus.—Dr. Meachen also read notes and showed a water-colour drawing of an Anomalous Form of Quinine Eruption.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on Feb. 13th, Dr. M. G. Biggs, the President, being in the chair.—Miss C. M. Parker, of the Ealing Training College for the Deaf, gave a demonstration on Lip-reading, illustrating it by means of a deaf mute. Miss Parker, after explaining the method of teaching lip-reading and showing the readiness with which it was acquired, spoke as to its value not only to those who were entirely deaf but also to the partially deaf, enabling such to follow conversation, the play, and the like, the greater part of which was usually lost to them, thus giving them an interest in their surroundings. It also avoided the necessity of loud speaking, especially to the detriment of the voices of children. The pupil had made remarkable progress and had none of the dull and apathetic appearance so common in the deaf.—Mr. Cecil Lyster showed some cases of Rodent Ulcer and of Lupus treated by the X Rays which had been very markedly improved by repeated exposures. A large tube was used for not more than ten minutes at a time at a distance of not less than six inches About seven exposures appeared to be sufficient to produce a good scar, the surrounding healthy tissue being protected by lead foil. Occasionally with too long or too close exposures a temporary dermatitis was produced. He considered that the best results were obtained by using a Wimshurst influence machine for producing the rays.

HUNTERIAN SOCIETY.—At the annual meeting, held on Feb. 13th, the following officers were elected for the ensuing year:—President: Dr. J. Dundas Grant. Vice-Presidents: Sir Hugh Beevor, Bart., Dr. Patrick Manson, Mr. H. J. Sequeira, and Mr. F. R. Humphreys. Treasurer: Dr. R. Hingston Fox. Trustees: Dr. H. I. Fotherby and Mr. F. M. Corner. Honorary librarian: Dr. T. H. Arnold Chaplin. Orator: Dr. A. T. Davies. Secretaries: Mr. J. H. Targett, and Dr. T. Glover Lyon. Editorial secretary: Dr. W. Rawes. Council: Dr. W. A. Dingle, Dr. W. J. Ettles, Dr. Fortescue Fox, Mr. A. W. Galloway, Dr. D. W. Goodall, Dr. Harold J. Johnson, Dr. W. H. Kelson, Mr. W. C. M'Donnell, Dr. J. W. Oliver, Dr. F. J. Smith, Dr. J. H. Sequeira, and Dr. T. G. Stevens. Auditors: Mr. F. Gordon Brown, Mr. Hope Grant, Dr. S. H. Appleford, and Dr. W. Rawes. After the annual meeting Mr. John Poland delivered the society's Oration, his subject being "A Retrospect of Surgery during the Last Century."

WIGAN MEDICAL SOCIETY.—The annual meeting of this society was held on Feb. 14th. Dr. Blair was voted to the chair.—A vote of condolence to the King and the Royal family was passed.—A vote of condolence to the relatives of the late Mr. G. Morris of Skelmersdale was also passed.—The following were elected office-bearers for the ensuing year:—President: Mr. William Latham. Committee: Mr. Latham, Mr. Mitchell Roocroft, Mr. Brady, Mr. Blair, Mr. Benson, Mr. Graham, Mr. T. M. Angior, and Dr. R. P. White. Honorary treasurer: Mr. E. H. Monks, J.P. Honorary secretary: Mr. William Berry.—The annual dinner was afterwards held and there was a very good attendance of members and visitors, including Sir William Mitchell Banks, Dr. J. Barr (Liverpool), Mr. D. A. O'Sullivan (Southport), Dr. T. E. Hayward (Haydock), and Dr. J. Reid (St. Helens).

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The fifth meeting of the session was held in the Medical Library of University College on Feb. 13th, Dr. D. S. Davies, the President, being in the chair.—Dr. W. H. C. Newnham showed two specimens of Fibroid Tumour removed by intraperitoneal hysterectomy.—Dr. Aust Lawrence, Mr. Munro

Smith, Mr. R. Williams, Dr. W. C. Swayne, Mr. Paul Bush, and Dr. W. K. Wills spoke on the subject.—Dr. F. H. Edgeworth read a paper on a case of Purpura Hæmorrhagica.—Dr. T. Fisher, Mr. J. Ewens, and Dr. Swayne commented on the paper.—Dr. H. Waldo read notes on a fatal case of Hæmatoporphyrinuria.—Professor Stanley Kent remarked on the case.—The President made a communication relating to Plague and introduced to the society Professor Stanley Kent who spoke on the subject and showed Microscopic Specimens and Cultures.

MIRFIELD AND DISTRICT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Memorial Hospital, Mirfield, on Feb. 13th, Mr. J. A. Erskine Stuart being in the chair.—Dr. A. G Barrs (Leeds) read a paper on the Minor Degrees of Circulatory Failure and their Treatment, in which he discussed the possibility of many disturbances at present attributed to high arterial tension being really due to the opposite condition. He also called attention to the circulatory origin of many symptoms which were usually ascribed to defects in the nervous and digestive systems.—Dr. Stuart, Dr. Sproulle, Dr. Tait, Dr. Stewart, and Dr. Milne discussed the paper, and Dr. Barrs replied.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—At a meeting of this society, held at Paddington Green Children's Hospital on Feb. 15th, Mr. Watson Cheyne being in the chair, 32 new members were elected, while the names of 20 candidates for membership were submitted to the meeting as having been approved by the council. A loyal address to the King, expressing the respectful sympathy of the members in the loss sustained by the death of Her Majesty Queen Victoria, was passed, the members all standing.

Reviews and Notices of Books.

Twentieth Century Practice: an International Encyclopædia of Modern Medical Science. By Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D. Volume XX.: Tuberculosis, Yellow Fever, and Miscellaneous. London: Sampson Low, Marston, and Co. 1900. Pp. 906.

WITH this volume the Twentieth Century Practice reaches its appointed end; it now forms a vast work presenting an excellent summary of our present knowledge of medical science. We do not pretend to give an exhaustive review of the volume now before us, but we wish to draw attention to some of its leading features in the way that we have done in dealing with its predecessors.

The subject of Tuberculosis is divided into four sections, each by different authors. The first deals with its bacteriology, pathology, and etiology and is written by Dr. A J. Lartigau of New York. After an interesting historical survey the author proceeds to give a very complete account of the bacillus tuberculosis, its tinctorial reactions, morphological characters, biology, and cultural characteristics, and then describes the distribution of tuberculous lesions in the body, the histogenesis of the tubercle, and the general pathology of pulmonary tuberculosis. It is most difficult to arrange a satisfactory classification of the various types of pulmonary tuberculosis. The disease may present itself under so many different guises that any classification based on sharp distinctions must necessarily not include a large series of intermediate forms in which are often seen the characteristics of several types. For the sake of simplicity and clearness Dr. Lartigau considers tuberculous inflammations of the lungs under two main headings, miliary tuberculosis and tuberculous pneumonia or "phthisis." This requires several subheadings and consequently the arrangement is not always very clear, but nevertheless after a perusal of the pages devoted to this subject the reader should be possessed of a concise idea of the various pathological changes which may be brought about by the presence of the bacillus of tuberculosis in the lungs.

The remarks on Modes of Infection of tubercle will doubtless receive a considerable amount of attention and we would especially draw attention to the section headed "Inhalation Tuberculosis." The experiments of Villemin, Cornet, and Tappeiner, among others, are considered; the results of some of these would appear to be contradictory, but it is shown that not only can infection be conveyed by the dry sputum carried into the air in the form of dust, but the act of coughing on the part of a consumptive patient is sufficient to contaminate prepared glass slips placed in his neighbourhood.

The symptomatology of tuberculosis is well described by Dr. H. W. Berg of New York, and the diagnosis, prognosis, prophylaxis, and treatment by Dr. J. A. Knopf of New York. The hygienic treatment is minutely detailed and is considered by the author to be the one which has thus far proved the most efficacious and which can be carried out in nearly all climates. Most physicians will agree with the author's remarks on the drug treatment of pulmonary tuberculosis when he says: "There is hardly any substance in the materia medica which at some time or other has not been recommended as an anti-tuberculous remedy. While I do not believe in going to extremes, saying that we can treat pulmonary tuberculosis without any medicinal substances, I think, nevertheless, that we may reduce their number to relatively few." Such is probably the result of all those who have had a large experience in the therapeutics of this disease. Symptomatic treatment stands on rather different grounds and good results may be obtained in correcting anæmia, indigestion, diarrhœa, and in relieving pain and cough.

The article on Yellow Fever is by Dr. Wolfred Nelson of New York. The remarks on bacteriology are instructive. The author has taken much trouble in collating the work which has been done with a view to isolate the pathogenic organism of this disease. After a review of the results published by various investigators he is forced to agree with Agramonte, who is of opinion that the pathogenic microorganism of yellow fever still remains unknown, notwithstanding the reports of observers who believe they have discovered it. He believes that the icteroid bacillus of Sanarelli has no further connexion with it than the bacillus coli communis, and gives his reasons for arriving at a conclusion which is contrary to the beliefs of many competent authorities. Some of these reasons would appear to be powerful ones; for instance, he states that the icteroid bacillus has been found in the tissues of individuals who died from other diseases distinct from yellow fever. If this can be definitely established it would, of course, directly discredit the bacillus as being the essential factor in the causation of yellow fever. Further, Agramonte maintains that the bacillus of Sanarelli does not agglutinate the serum of patients or of convalescents from yellow fever, and that the serum of convalescents from yellow fever does not protect against infection by the icteroid bacillus. It is evident that new methods and new media must be employed in future investigations before the bacteriology of this disease can be definitely established.

Dr. Thomas R. Brown writes an interesting paper on Poisoning with Snake Venom. He attributes death in snake poisoning to the following causes: (1) general paralysis, especially of the respiratory centres; (2) paralysis of the heart by tetanic arrest of cardiac action, probably due to the action of the venom upon the cardiac ganglia; (3) a combination of these causes; (4) hæmorrhages in the medulla; and (5) possibly the inability of the red blood corpuscles to perform their function. With regard to the treatment of snake-bite by antivenene Dr. Brown believes that the practical results so far obtained are of great promise and

thinks it quite possible that a real antidote to snake poison has at last been found.

A short article by Dr. Beaumont Small of Ottawa on Mushroom Poisoning is well worthy of perusal, as is one by Dr. James E. Newcomb of New York on Diseases of the Uvula, Soft Palate, and Faucial Pillars.

The final contribution is by Dr. Francis Warner, on Neural and Mental Defects in Childhood. Dr. Warner's valuable investigations on this subject are well known in this country and the present article summarises his views, which have had, and will continue to have, great weight in all matters dealing with education.

The volume terminates with a general index to the whole work, and in the preface to this volume the editor thanks Dr. Emma E. Walker of New York for the valuable assistance she has rendered in this part of the work. The amount of work entailed in the preparation of this index may in some measure be estimated by the fact that it occupies over 300 pages. We congratulate the editor of the "Twentieth Century Practice of Medicine" on the completion of his task. The whole work has been carried out in an admirable way and will form one of the most important medical works of reference in the English language.

Modern Surgery, General and Operative. By JOHN CHALMERS DA COSTA, M.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia; Surgeon to the Philadelphia Hospital. With 493 Illustrations. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 1118. Price 21*s*.

WE reviewed the second edition of this work in 1899 and we can speak even more favourably of the present issue. It contains 200 more pages and 100 more illustrations, and may be said to be fully abreast of the knowledge of to-day. The increase in extent has enabled the author to describe more fully many subjects and numerous small alterations have been made which considerably improve the text. The addition of so large a number of illustrations accounts in part for the general increase in the size of the volume; they are judiciously selected and will prove useful to the student. A few of the illustrations are unsatisfactory; for instance, Fig. 430 on p. 1053 is supposed to represent compression of the aorta by an assistant. If the figure shows anything it certainly shows compression of the external iliac artery immediately above Poupart's ligament, or even compression of the common femoral. The point compressed is altogether too low for even the bifurcation of the aorta.

A very good though brief account is given of Gunshot Wounds, and we would especially praise the section on the Use of the Roentgen Rays, in which the author describes Sweet's apparatus for localising foreign bodies. This is a good method, but it involves more trouble than that introduced by Davidson. The index is elaborate and, so far as we have tested it, exact.

A Manual of Midwifery. By ALFRED LEWIS GALABIN, M.A., M.D. Cantab. Illustrated with 298 Engravings. Fifth edition. Crown 8vo. London: J. & A. Churchill. 1900. Pp. 870. Price 15*s*.

THE appearance of a fifth edition of this well-known Manual of Midwifery is to be welcomed. In so widely read a book as this it is essential that successive editions should follow one another with sufficient rapidity to prevent its becoming out of date. The fact that the first edition only appeared in 1886 shows that in the present instance this has been done. The book retains all its prominent features. We imagine the various sections upon the mechanical action of the sacrum, the development of the pelvis, and the leverage action of forceps, containing, as they do, many mathematical considerations, will continue in the future, as in the past, to be skipped by the average student. None the less, they are of great interest and have always been one of the features of the work. The chapters in the present edition that have required most alteration are those upon Extra-Uterine Fœtation, Septicæmia, and Deciduoma Malignum. It is interesting to note that Dr. Galabin's opinion that ovarian gestation is possible may be held to be proved by van Tussenbroeck's case. The classification of ectopic gestation has not, we think, been altered since the first edition, and possibly in time all the forms recognised by the author may be demonstrated as undoubtedly occurring, although even now there are many who question the possibility of primary abdominal fœtation. The bacteriology of puerperal septicæmia is fully considered and the chapter is a good *résumé* of the most recent work upon the subject. We are glad to see that curettage after delivery is condemned and that the performance of hysterectomy in cases of septic infection is regarded with doubt. The author conclusively shows by the mathematical doctrine of probabilities that there is a definite causal relationship between cases of hydatidiform mole and cases of deciduoma malignum. He points out that the nucleated masses of protoplasm seen in some cases of sarcoma of the testis do not form the branching reticulated processes, resembling the proliferating syncytium of villi, which are figured in cases of deciduoma malignum. He considers that the cells of the growth, as well as the protoplasmic masses, are derived from the syncytium of the villi, a view held by Whitridge Williams. This is the more probable, since in many instances there is no absolute demarcation but rather a gradation between syncytium and plainly discrete cells. Some very interesting micro-photographs are given, showing a possible gradation between portions of retained placenta, vesicular mole, and deciduoma malignum. 29 new figures have been added. The whole book shows evidence of careful revision and is well calculated to maintain the high reputation gained by the previous editions.

Atlas Seltener Ophthalmoscopischer Befunde zugleich Ergänzungstafeln zu dem Atlas der Ophthalmoscopie. Von Hofrath Dr. J. OELLER, Professor an der Universität München. Erste Lieferung. 5 Tafeln mit Text. (*Atlas of Rare Ophthalmoscopic Conditions and Supplementary Plates to the Atlas of Ophthalmology.* By Hofrath (Privy Councillor) Dr. J. OELLER, Professor in the University of Munich. The text translated into English by THOMAS SNOWBALL, M.A., M.B. Aberd. Part I., 5 plates with text.) Wiesbaden: Verlag von J. F. Bergmann. Glasgow: Obtainable from F. Bauermeister. 1900. Price 8*s*.

IN the course of last year Professor Oeller completed an atlas of the ordinary diseases of the fundus of the eye, exhibited in 75 plates. The present part is the first of a volume intended as a supplement to that work, which will run to about five parts, each containing five plates. The parts are to be published at irregular intervals as material accumulates and will contain accurate representations of rare and exceptional forms of disease. The divisions of the work will be understood when it is said that the plates will comprise the appearances presented by the normal fundus, the diseases of the optic nerve, the diseases of the retina, the diseases of the choroid, and, finally, congenital anomalies. The plates are very beautifully executed in chromo-lithography and display very minute and delicate details. The first plate is one showing apoplexy of the retina with endarteritis obliterans, thrombosis of the inferior temporal vein, and retinitis circinata. It is of particular interest because it depicts the later condition of a patient whose eye had already been drawn in the atlas of Professor Oeller. Such supplementary illustrations are rare and for that very reason extremely valuable. They give the information which it is particularly desirable that the

ophthalmic surgeon should possess. A considerable number of practitioners, thanks to the excellent cliniques attached to most of our medical schools, are quite competent to recognise the actual conditions that are present in any particular case, but they look to the professed ophthalmologist to give them a reasonable or probable forecast of the future, and to give this he must be guided by his own notes or drawings, or if he be unable to sketch from nature by the illustrations of so accomplished a draughtsman as Professor Oeller, by whom all the plates in this part have been made. In each case, after the description of the appearances presented is given in German, a faithful translation follows by Dr. Snowball of Aberdeen. The first plate affords strong evidence that degeneration of the vascular walls constitutes an important factor in the development of retinitis circinata. The second plate exhibits striæ and detachments of the retina and of the vitreous humour following a wound implicating the sclerotic, choroid, and retina and succeeded by a hæmorrhage, the appearances presented being those seen in the inverted image after the hæmorrhage had undergone absorption. Professor Oeller considers that the striæ, which form a marked feature of the drawing, are formed from individual folds of a previously detached retina which have never become quite smooth but have degenerated into connective tissue. The third plate exhibits the aspect of a case of chorio-retinitis albuminurica. The fourth is a case of staphyloma posticum congenitum with a remarkable vena vorticosa which is lost to view in a groove situated in the white staphylomatous crescent. The last of the five plates is a representation of a disc with an optico-hyaloid cone projecting from it. It appears to be stationary, as no change has been observed in it for several years. If the promised parts contain drawings of equal interest with those now issued the volume will prove a very valuable accession to ophthalmoscopic literature. Messrs. Bergmann may be complimented on their fine reproductions of Professor Oeller's delicately finished coloured drawings. Is it impossible to get such plates executed in England?

LIBRARY TABLE.

Beiträge zur Beurtheilung der Bedeutung der Vaginalen und Sacralen Total-Extirpation des Uterus für die Radicalheilung des Gebärmutterkrebses. Von Prim. Dr. HERMANN VON ERLACH und Dr. HANS R. VON WOERZ. Wien: Seidel und Sohn. 1901. Pp. 112. 8vo. (*Contributions to the Discussion of the Value of Vaginal and Sacral Total Extirpation of the Uterus for the Radical Cure of Cancer of the Uterus.*)—Dr. Hans R. von Woerz records the results of 131 vaginal hysterectomies for carcinoma of the uterus. 10 patients, or 7·6 per cent., died as a result of the operation. Of the remaining 121 he was able to trace 115. Of these 62, or 53·9 per cent., were alive and well at the time the figures were collected. Four had died from other diseases and 49, or 42·6 per cent., had died from recurrence. No recurrence had occurred in any case after the lapse of three and a half years from the time of the operation. Of the cases which had remained well in 30 a period of more than three and a half years had elapsed since operation. The frequency of recurrence in cancer of the porto-vaginalis he found to be 43·7 per cent., in cancer of the cervix 50 per cent., and in cancer of the body of the uterus 18·2 per cent. Dr. Hermann von Erlach in his paper gives the results of 27 cases of cancer of the uterus operated upon by the sacral method. Five patients died as a result of the operation, four could not be traced, and one died from tuberculosis. Of the remaining 17 patients 10, or 59 per cent., died from recurrence, while seven, or 41 per cent., remained alive and well. Of these in four cases more than three and a half years had elapsed since operation. The indications for and against vaginal hysterectomy and the sacral operation are discussed by the authors.

Sanity of Mind: a Study of its Conditions and of the Means of its Development and Preservation. By DAVID F. LINCOLN, M.D. New York and London: G. P. Putnam's Sons. 1900. Demy 8vo, pp. 184. Price 5*s*.—This is a type of book of which the present day is peculiarly productive, but, unlike many others of its kind, it deserves notice, both for the matter which it contains and for the form in which it is presented. It deals in a somewhat discursive but suggestive way with the important problems of education, heredity, mental degeneracy, and insanity. The theme is presented in such a form that it can be readily apprehended and appreciated. There is something in the mental attitude of our day which makes it easier to discuss the problems touched upon in this book than it was a generation ago. We have outlived the period of metaphysical analysis and classification; we have begun to study insanity, not merely as philanthropists, but from the point of view of husbanding the State's resources and of extinguishing the evil by practical legislation. This attitude is shown throughout the book. The subject of degeneracy is especially well treated by the author and many judicious observations are made on education and mental development. The concluding chapter deals with social and civic duties. This little work deserves careful reading; it appeals alike to the cultured layman, the psychologist, and the physician as the product of a thoughtful mind keenly alive to the medico-psychological and social problems of the day. The writing is throughout marked by lucidity and even grace.

St. Bartholomew's Hospital Reports. Vol. xxxvi., 1900. Edited by NORMAN MOORE, M.D. Lond., and D'ARCY POWER, F.R.C.S. Eng. London: Smith, Elder, and Co. 1901. Pp. 350 + 240.—The volume of these reports for 1900 opens with two obituary notices, the one by Mr. Howard Marsh of Sir James Paget and the other of Sir R. Thorne Thorne. In all there are 19 original articles, of which perhaps the most striking are that by Mr. D'Arcy Power entitled "The Lessons of a Year's Surgical Experience"; a Case of Landry's Paralysis, by Mr. J. Preston Maxwell; and a Case of Myasthenia Gravis with Autopsy, by Dr. F. E. Batten and Dr. H. Morley Fletcher. Mr. Preston Maxwell considers that the case reported by him supports the view that Landry's paralysis is due to a toxin acting upon the motor neurons of the spinal cord. The case was that of a Chinese woman, aged 62 years, who took to opium smoking for the relief of pain and who, although she had never smoked before, began with half a drachm a day, a dose which was continued for 10 days when itching of both feet and obstinate constipation ensued. She had felt no narcosis, but the pipe was stopped and two days later she began to lose power over her feet. The usual statistical tables and details of additions to the museum make up the volume.

Chirurgie du Rein et de l'Uretère. Par le Professor JAMES ISRAEL, chirurgien principal de l'Hôpital Israélite de Berlin. Traduction du Dr. GUILLERMO RODRIGUEZ, de Valparaiso. Préface du Dr. J. ALBARRAN, professeur agrégé à la Faculté de Médecine de Paris. Avec un résumé de 230 opérations rénales, 2 planches en couleur, et 2 gravures intercalées dans le texte. (*The Surgery of the Kidney and the Ureter.*) Paris: Société d'Éditions Scientifiques. 1900. Pp. 210. Price 7 fr. 50 c.—Professor Israel's "Surgery of the Kidney and Ureter" is well known to all who have especially devoted their attention to this subject, but its value would have been more extensively appreciated if more surgeons in this country were able to read German. Therefore we welcome the appearance of this French version, for the latter language is more widely understood. The work is based on 81 operations on the kidney and ureter

performed during the 10 years 1882 to 1892, and complete tables are supplied containing particulars of all these cases. All the opinions expressed are those held by Professor Israel himself, for very little space is devoted to the discussion of controverted points. The translation is good and the book should prove of interest to many readers.

Practical Household Cookery Recipes. By A. M. WESTCOTT. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1900. Pp. 94. Price 1*s*.—This little book contains household recipes, most of which seem very good. There is a section which more nearly concerns medical readers—namely, that headed "Invalid and Convalescent Cookery." In this good recipes are given for such dishes as the various forms of beef-tea, barley-water, lemonade, and other suitable foods for invalids. With regard to the recipe for lemonade, we think that the juice of one lemon is a rather small allowance for one and a half pints of water, although lemons are not uniform in size; also, in our opinion, it is better, in order to get the flavour of the oil of lemons, to grate the peel after the lemon has been washed than to pare it off with a knife. If pared the lemonade is almost sure to have a slight flavour of the steel knife and it is difficult to avoid getting some of the white portion of the peel which makes the lemonade taste bitter.

The Convalescent's Diet. By LUCY HELEN YATES. London Virtue and Co. 1901. Pp. 96. Price 1*s*.—This is a sensible little book and the introduction is practical. On p. 19 we find the following, which at first sight is startling: "We find iron very largely in spinach ..... mercury also contains it." It would be as well, we think, in future editions to substitute the words "herb mercury" and explain what herb mercury is. We suppose that Miss Yates means the *Chenopodium Bonus-Henricus*, or Good King Henry, which is sometimes used as a substitute for spinach. The *Mercurialis* which belongs to the *Euphorbiaceæ* is not, so far as we know, used for food. The recipes seem very good, but we cannot agree with the statement on page 9 that rabbit is digestible. Some persons can digest it and some cannot, the ability to do so being a matter of idiosyncrasy.

JOURNALS AND MAGAZINES.

IN the *Medical Magazine* for February Mr. J. Foster Palmer concludes his articles upon Modern Epidemics and is hopeful that in the future typhoid fever will be abolished to the same extent that typhus fever has been. His sanguine expectations are based more upon the efficacy of general sanitation than on the influence of personal measures such as inoculation, though with regard to the latter he holds definitely favourable opinions. Mr. Edmund Owen contributes a short but discursive article on Some Tuberculous Affections of Children and Dr. Allchin continues at some length to consider the reconstruction of the University of London. Another university, that of Oxford, is pleasantly, but without much profit, considered by Mr. J. H. Crespi, who discusses this ancient seat of learning as an entrance to the medical profession. The matter is not very deeply entered upon, as the writer strays easily into pleasant quadrangles and is drawn away by the social fascinations of undergraduate existence. The Suppression of Malaria is the subject of an article by Dr. Arthur R. Waddell, who makes interesting observations upon this problem as it affects the enormous areas of Asia and the more confined ones of European malarious districts.

In accordance with the methods laid down for its future in the January number of the *Practitioner*, one special subject is considered in all the chief original articles of the February issue, the subject being Medical Examinations for Insurance. Dr. T. Colcott Fox considers the special functions of the medical examiner and his conclusions are in the main the same as those arrived at from the opposite point of view by Mr. James Chisholm. Both are undoubtedly right in affirming that what is wanted from the medical examiner is a record of: (1) facts of the patient's case from all medical points of view; and (2) the impressions of the examiner. Mr. Chisholm, however, thinks that no judgment is required as to expectation of life, this being left to the combined judgment of the chief medical officer of the company and its actuary. Mr. Chisholm's long article will be read with much benefit by all medical men who are called on to make these examinations. He thinks that it is unwise for the usual medical attendant to be an examiner of his patient. We quite agree with him. Dr. T. Glover Lyon gives model forms for life assurance as drawn up by the Life Assurance Medical Officers' Association. Dr. J. J. Perkins discusses the purely medical aspects of life assurance in a comprehensive article, and Mr. J. Jackson Clarke deals similarly with the surgical side of the matter. Some of Mr. Clarke's deductions, if carried to their logical limit, seem to us hard upon candidates. In his view hammer-toe, for instance, as an indication of rheumatoid arthritis would considerably prejudice a "life." Thomas Sydenham, as the Medical Hero of the Month, is the subject of an attractive little article that is in the main abstracted from Dr. J. F. Payne's admirable book on the famous physician. Dr. Arthur Newsholme's conclusion on the Influence of Soil on the Prevalence of Pulmonary Phthisis is that this influence is limited to the action of wet soils as a predisposing cause through the tendency to catarrhs of respiratory mucous membranes that such soils occasion. Dr. H. D. Rolleston discusses Recent Literature on Diseases of the Digestive Organs—congenital pyloric obstruction, tumours of the appendix, and chronic pancreatitis being the most important conditions referred to.

New Inventions.

SANITARY PAVING MATERIAL.

WE have received specimen blocks of a sanitary paving material for which several important claims are made. Already this material has been employed in many large and busy streets with satisfactory results after several years' trial. We have carefully examined specimen blocks taken up from a busy thoroughfare in London where they had been laid down in 1897. From a section of one of these blocks it is quite clear that the material is absolutely non-absorbing. The "business" surface of the blocks was just veneered with a film of the usual road deposit which readily detached on passing a stream of water over it, leaving it quite clean. The blocks are exceedingly heavy and are denser than the hard woods commonly employed for the same purpose. They appear to consist of small pieces of granite fixed in a bitumen-like bed. The compost is nearly black and the surface practically radiates no light or heat. Apparently the blocks never wear smooth to a slippery degree and thus they afford an excellent foothold for the horses while at the same time they become sufficiently smooth to render traffic as silent as possible. The surface is easily cleansed. It is stated that the blocks being laid closely together the small space between them is soon closed by compression under traffic which prevents the ultimate absorption of noxious liquids. It seems to us that any noxious liquid that might leak in at first would be enclosed by the same process. However, an examination of blocks that have been in use for three years scarcely justifies the view that liquid sweepings are thus enclosed, but rather that the spaces are so quickly closed as to avoid this possibility. The material is exceedingly durable and, as far as we are able to judge, excellently adapted for the purpose, chiefly because of the cleanly state of the street which its use as a paving roadway should secure, assuming that the blocks are properly laid. Its properties are such as to reduce to a minimum the formation of mud and dust. The Sanitary Block and Tile Pavement Company, Limited, of 17, Victoria-street, Westminster, supply the blocks.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 23, 1901.

The Constitution of the British Medical Association.

IT has been apparent for some time past that the British Medical Association is not in a state of rest. It is prosperous in the sense of numbers, its annual meetings are successful, and its journal maintains its high character. But for various reasons there has been a feeling of antagonism between the executive of the Association—i.e., its Council—and a considerable section of the members of the Association. The dissatisfied members have complained of absence of sympathy on the part of the Council with the views and wants of the rank and file of the Association, and also of the need of effective means for bringing the Council more into contact with the members and for subjecting it more effectively to the wishes of the members in the promotion of their views of policy. This antagonism came to a crisis in July last, when it was proposed to make the Council as far as possible the only authoritative body in the Association under a new set of articles of association. This proposal of the Council failed to secure support at an extraordinary general meeting of the Association; and at a general meeting held at Ipswich during the annual congress of the Association a strong committee was appointed to consider and to report upon the "best means of reorganising the constitution of the British Medical Association."

The provisional report of this committee, known as the Constitution Committee, is given in the form of a supplement to the *British Medical Journal* of Feb. 16th. To understand its essential proposals it is necessary to be familiar with the existing constitution of the Association. This cannot be set out in the course of an article, while it is familiar to most of our readers. It will be sufficient to recall the salient features. The present working organisation of the British Medical Association consists practically of the Council and the branches. The Association is believed to have over 17,000 members. Only two-thirds of these are members of the branches. The Association is actually a limited company and its Council practically a board of directors. The majority of the members of the existing Council are elected by the branches, but Vice-Presidents and officers add materially to its composition. The branches are of varying size and cover areas of varying size. They are often referred to by the Council for their opinion, but their decisions need not be followed by the Council. An annual meeting is held, and the time is mostly occupied with scientific discussions and social functions. But three general meetings of the members are also held during the annual congress, and at these the business of the Association is discussed upon the presentation of the annual report and the statement of accounts. Resolutions are passed by the members at these general meetings and, according to counsel's opinion, the Council is bound to give effect, as a general rule, to such resolutions if due notice be given of the motions from which they arise. The counsel of the Association, Mr. FRANCIS B. PALMER, in April of last year expressed the opinion that to give such powers to general meetings, which are often small and fortuitously composed, is "unsuited to a concern of this magnitude and exposes the interests of the members at large to grave peril." Both the Council of the Association and the members who most actively resented the new articles suggested by the Council seem to have agreed that the general meetings of the Association were not suitably organised for the expression of the views of the great body of members. The perception of this by two parties in the Association, taking for the most part different points of view, has led to the chief suggestions of the Constitution Committee.

The Constitution Committee in their report propose a scheme of which the following is a summary. They contemplate a change in the constitution of the Council, reducing the number of *ex-officio* members, and making it more representative of the rank and file of the Association. Units of local organisation, corresponding for the most part to Parliamentary divisions, and so covering areas of moderate extent, are to be created, and the divisions are to be grouped to form branches. Henceforth there are to be no unattached members of the Association, but every member of the Association is *ipso facto* to be a member of the division in which he resides and will have no excuse for not attending the meetings of that division. The most striking recommendation of the Constitution Committee has reference to the means for giving importance to the opinion of divisions. Obviously the divisions are too numerous to send representatives to the Council. But each division is to be empowered to elect annually a delegate, who will represent the division at a meeting of delegates to be held annually at the same place and time as the annual general meeting of the Association. This meeting of delegates is to have special charge of medico-ethical questions and will have to consider reports of the Council and other matters connected with the business side of the Association, finance and the editorial management of the journal being expressly placed without its jurisdiction. Much is expected of the delegates under the new scheme. They will be required to vote on every question in accordance with the views of their constituencies expressed in resolutions at divisional meetings within a period of three preceding months. The delegate is to have a vote according to the numbers of his division, so that one delegate will differ from another delegate in importance. The quorum of the annual meeting of delegates is to be one-half of the total number of delegates, and their resolutions to be binding on the Council must be carried by a majority of two-thirds. The vote of the annual meeting of delegates on the subjects within their competence is to be guiding as a matter of policy on the Council, who, however, are to be given a power of *referendum* where it is of opinion that the delegates have exceeded their powers or

have recommended a course that would be injurious to the interests of the Association. The travelling expenses of delegates in attending the annual meetings will be paid out of the funds of the Association and will come to a very considerable sum—perhaps £3000 per annum.

Working constitutions are not made by abstract resolutions, and we heard with concern of the duty imposed on some two dozen gentlemen to "reorganise the constitution" of the British Medical Association. According to our view, a constitution has to be evolved, to grow, to be altered and adapted from time to time to meet new circumstances. The question is whether the scheme of the Constitution Committee of the British Medical Association is one of natural evolution. We doubt it. We are impressed with the boldness of those who have cast the constitution of a prosperous Association into the melting-pot. But we hasten to say that the report of the committee and the discussions which led up to it are imbued with moderation and a sense of responsibility. A respect for the views of others is shown that is worthy of the occasion and forms the best argument for the committee's recommendations. We hope that the report will be considered carefully by the branches and that, if the scheme of the Constitution Committee is adopted in whole or in part, the innovations will be given a trial in the same spirit of moderation as that in which they are put forward. Otherwise we should expect the executive of the Council to suffer and in time to be composed of inferior men, who would be the willing victims of dictation and delegation. It is this aspect of the report which most demands attention.

The Housing of the Working Classes in London.

THE housing of the working-classes is not only one of the most urgent questions from a medical point of view now clamouring for attention from the Legislature, but it is also a question in which the KING takes a deep personal interest. The London County Council has attempted to put before the public a complete history describing what has been done in the metropolis for the h using of the working-classes, and in view of the reference made to the whole matter in the Speech from the Throne the action of the Council is seen to be very opportune. The volume published by the Council formed the basis of a series of articles which we recently published.[1] But the subject is so complicated and of such extreme medical importance in so many directions that we make no excuse for recurring to it. Its difficulty is well proved by the fact that even Mr. C. J. STEWART, the clerk of the Council, Mr. W. J. RUSSELL, and Mr. M. H. COX, LL.B. Lond., who together prepared the volume in question, had great difficulty in obtaining correct figures, especially in regard to the actual numbers of persons for whom new and better dwellings have been or will be provided. So many records have been kept, drawn up at different times by different authorities and embracing various schemes or sections of schemes, that the figures given fail to agree. Indeed, it was not until after the bulk of the work had gone through the press that a final and corrected set of figures was obtained and added in an Appendix. Hence the statistics given in different parts of the book do not tally, the figures, for example, on page 328 do not agree with the figures published on page 43. If those who are at the very fountain-head of information may thus be led into error it is no wonder if outside critics are at fault. Yet if we abstain from detail and content ourselves with a broad generalisation the position becomes sufficiently clear for practical persons to discuss it, and the acrimony that has been imported into the question by some seems to us quite unnecessary. To recapitulate the facts briefly, the Metropolitan Board of Works cleared 51 acres of insanitary areas on which 29,056 persons were living. It did not itself attempt to re-house these persons, but sold the land to artisans' dwellings companies for some £377,000. This left a loss on the cost of the clearances of £1,605,088, money which the ratepayers have to pay and for which no direct financial return will be obtained, though indirectly, there will accrue all the advantages which result from a general improvement in the public health. The companies to whom the Metropolitan Board of Works sold this land re-housed 27,780 persons. When in 1889 the County Council replaced this authority the artisans' dwellings companies had exhausted their powers of action, and no one could be found to purchase the land on which clearances had been or were to be made for the carrying out of the legal obligation to build only workmen's dwellings. Therefore the County Council had to replace private enterprise and itself build and let out in tenements the required dwellings. At a dead loss of £1,045,050 the County Council cleared 31 more acres and the local vestries nine more acres, making, with fractions added, a total clearance since 1875 of 94 acres. The County Council have re-housed or provided for the re-housing of 34,196 persons and the vestries have similarly dealt with 2452 persons, giving (with the 27,780 persons mentioned above) a grand total of 64,428 persons who have been or will be re-housed by the schemes adopted since 1875 and up to March, 1900. Since then further schemes have been adopted by which probably some 3000 more persons will be housed. More land is being purchased for this purpose.

Such are the facts, and though they represent a very vast undertaking its insufficiency to deal with the problem of housing the London poor is painfully evident. The population of London is said to have increased to the extent of 700,000 since 1881. This means a "submerged tenth" amounting to 70,000. There must be in the metropolis by this time some 500,000 persons who cannot afford to pay a sufficiently high rent to secure healthy houses. The common lodging-houses may provide for from 28,000 to 30,000 of these, and the workhouses and workhouse infirmaries for a larger number. The number of paupers in the metropolis during last year was estimated at 125,000. Still a formidable balance remains. To put the matter crudely, the question is whether the ratepayers of London are going to pay a portion and in some instances the whole of the rent for the housing of about 500,000 persons. If not, how are these people going to be compelled to live in healthy

[1] THE LANCET, Jan. 12th (p. 124) and 19th (p. 205), and Feb. 2nd (p. 351), 1901.

homes? The position seems hopeless if only because of the extravagant cost of effecting the clearances and of purchasing land and houses. With the exception of the inmates of the workhouses and those few who contrive to sleep on doorsteps, in the parks, in passages of houses, or in unlet vacant houses, all these extremely poor people not only pay rent but, in comparison with the accommodation given, very high rent; while all enterprise directed towards providing them with decent accommodation at moderate prices is handicapped by heavy initial expenses. For clearances effected under Part I. and Part II. of the Housing of the Working Classes Act of 1890 there are clauses tending to reduce these expenses, but the places cleared must first be condemned as insanitary; and the land must be sold though there may be no purchasers forthcoming even when the land is offered at a quarter or a third of the cost of effecting the clearance. When purchasing land under Part III. of the Act the local authority may retain it in perpetuity, but then the system of compensation is that set forth by the Lands Clauses Consolidation Act of 1845. This means that unless a friendly agreement is made each side nominates an arbitrator. Both arbitrators receive a fee of 50 guineas for valuing the property and invariably they disagree. Then they appoint an umpire who charges 50 guineas a day. Expert witnesses are called and they cost about £40 each. The total expenses, with the solicitors' fees, rarely amount to less than £1000, and the entire property may not be worth more than £3000 or £4000. There is an unwritten law which sanctions an addition of 10 per cent. on the estimated value as a sort of compensation for disturbance. Thus it may safely be said that if a local authority wishes to buy under Part III. of the Act a property worth £4000, and fails to effect a friendly agreement, it will have to pay in all some £5000. Evidently there is need here for further legislation. The great cost of arbitration might be avoided by simply taking the rateable value of the property to be purchased as the basis of the compensation to be paid, but this is a drastic suggestion not likely to be followed unless the owners of London house property find their pockets actually affected by the difficulties arising out of the housing of the poor. The compulsory purchase at a very low price of such property as has become so degraded as to constitute a real danger to the public health ought, however, to be a legal possibility. When the speculator on the extreme misery of the poor has allowed his property to degenerate into a public nuisance and danger, what right has he to receive handsome compensation? On the other hand, seeing that the local authority can no longer sell the land it purchases under Part I. and Part II. of the Act, it should be officially recognised that it has the right to keep such land just as if it had been purchased under Part III. of the Act. Such powers would greatly lighten the difficulties of municipal enterprise, and it is all the more necessary to demand these facilities, as municipal enterprise is now the only form of enterprise which in London shows any disposition whatsoever to deal with the question.

If we have spoken at such length on the financial difficulties it is because they constitute the main obstacle to the housing of the poor and of the working-class. Though these are matters that should, strictly speaking, be dealt with by political economists, still the sanitary reformer is invariably met with financial objections raised against his proposals. So far as the purely sanitary aspect of the question is concerned there are no difficulties any longer. On the contrary, every metropolitan borough now possesses an able medical officer of health receiving a salary that secures his independence. All these sanitary officials have gone through the same training and possess a uniform and special technical knowledge of the laws of hygiene. So far as the work of the medical profession is concerned, all competent medical officers of health can speak out as with one voice. The conflict of opinion arises only when we quit the domain of sanitation to tread on the uncertain ground of political economy. Unfortunately the two are inextricably linked together. It does not suffice to condemn overcrowding, bad drainage, and ineffective ventilation. It does not suffice to say how houses should be built and drained. The money must be found before these improvements can be effected, and that is why the progress realised has been slow as compared with the necessities of the case. But it is satisfactory to feel that in future there will be no delay due to the health service of the metropolis. The London local authorities no longer content themselves with merely pretending to observe the law by paying a nominal salary to a medical man who best satisfied his employers when he did as little as possible. London can now boast of a really efficient staff of independent medical officers of health, and it will not be their fault if greater progress is not more rapidly accomplished than heretofore.

Some Points in the Metropolitan Water-supply of 1900.

THE December report on the condition of the metropolitan water-supply presented by the Water Examiner to the Local Government Board has just been published. The Thames water at Hampton, Molesey, and Sunbury was in good condition during the greater part of the month, but from the 1st to the 6th and from the 9th to the 28th days of the month it was more or less turbid. The engineer of the Chelsea Waterworks Company keeps a daily record of the state of the river at the intake of that company, and as the amount of water supplied to their customers is less than that which they are authorised to draw they are able when the river is in an unsatisfactory state to close their intake for several days at a stretch. According to the report of the engineer of the Chelsea Company the state of the water was "indifferent" on the 6th, 8th, and 29th days of the month, and "bad" on the 30th and 31st, and on four days during the month no water was taken from the river by the company. The East London Waterworks Company have an intake from the Thames and usually abstract from the river about 8,000,000 gallons per day. There is no reservoir for the storage of this water, and it therefore follows that water described by the Chelsea Water Company's engineer as "indifferent" and "bad" was presumably taken by the East London Company and allowed to pass straight to their filter-beds without undergoing any process of sedimentation. The

Water Examiner says in his report that all the samples of the water collected at the works of the companies were efficiently filtered. It is not, however, stated that the chemist employed by the Local Government Board collected any of the water which was obtained from the filter-beds of the East London Company during the time at which the natural river water was in an indifferent or bad condition. We should be interested to learn what the quality of the filtered water was on these occasions. It may, perhaps, be well again to point out[1] that the water from the Thames station of the East London Company passes through a main about 19 miles in length to a covered reservoir situated in Finsbury Park, and that the same reservoir is supplied also from the Lee Bridge station of the company. Armed with this knowledge the Water Examiner and chemist appointed by the Local Government Board will be able to see in what manner they can best obtain accurate information as to the state of the Thames-derived water supplied by the East London Company. It is true that neither the Water Examiner nor the chemist have any right of entry into the premises of any one of the metropolitan water companies, but it has many times been stated that no impediments have ever been placed to their access to all parts of the companies' works. It does not appear, therefore, that there is any reason why this matter, to which we have before called attention, should not be investigated at the earliest opportunity; that is to say, during the next period at which the water is turbid.

During the year 1900 little progress has been made by some of the metropolitan water companies towards giving a continuous supply of water to all their customers, a duty which they are now under a statutory obligation to perform. The Chelsea and Grand Junction Companies profess to give a constant supply to all their customers, and the East London Company to 99 per cent. of theirs. The Kent Company at the end of the year 1900 supplied 92 per cent., which may be compared with 91 per cent. supplied at the end of the year 1899. The Kent Company, it is fair to point out, supply a number of people who live at high levels on hills scattered over a considerable area. This cannot be said in the case of the Lambeth Company. At the end of the year 1899 this company gave continuous supply to only 75 per cent. of their customers, and at the end of the year 1900 they supplied only 76 per cent. It is much to be hoped that the local authorities, or the customers themselves, who now have power to insist on having a continuous supply, will use their privilege in this respect. The customers of this company cannot be congratulated on the way in which they allow themselves to be treated. Month after month we find that the water supplied by the Lambeth Company, as compared with the water of the other companies, exhibits the deepest average tint of brown, a fact which points to inadequate treatment of the Thames river water. It cannot be pleaded on behalf of the company that they are not sufficiently paid, for the charges which the company are allowed to make are higher than those allowed in the case of any other company. During the year 1900 the New River Company have extended their constant service to the extent of 3 per cent. of the total supplies—that is to say, 95 instead of 92 per cent. of all their customers now have a constant supply. It may be remembered that parts of the City of London had a short time ago only an intermittent supply, but it was stated that constant service was being largely extended. During the year no improvement in this respect has been made in the case of the Southwark and Vauxhall Company—93 per cent. of their customers had constant service at the end of December, 1899, and the same proportion at the same date in the year 1900. Of all the metropolitan companies the greatest improvement in regard to the giving of a constant service has been made by the West Middlesex Company, of whose customers 98 per cent. instead of 93 per cent. are now constantly supplied, an improvement of 5 per cent. of the total number.

The report of the Water Examiner shows that the tint of the water supplied by the companies has varied within considerable limits; the proportion of brown tint as seen in a two-foot tube ascertained by comparison with the standard tint of brown has ranged from 4 degrees to 18 degrees. Dr. THORPE, the chemist appointed by the Local Government Board, reports that all the samples taken from the mains of the Chelsea, West Middlesex, Southwark and Vauxhall, New River, and Kent Companies were clear. One sample each of the East London and Grand Junction Companies, and two samples of the Lambeth Company's water, contained a few particles of iron rust, and a sample of the Lambeth water taken at Brixton was finely opalescent and contained a minute trace of suspended inorganic matter and a few infusoria. It would be well if the Local Government Board were to make provisions by which their water analyst would be enabled to make a much larger number of examinations than he does at present. Any so-called economy displayed by the Local Government Board in declining to provide sufficient money for the proper payment of their skilled analyst would be a great mistake. It is essential for the interests of the water consumers of London that a thorough examination should be constantly made of the water which is supplied to them, and under the existing conditions the officers of the Local Government Board are allowed facilities for visiting the companies' works which are not possessed either by the County Councils or by any other metropolitan authority. Up to the present time we understand that no difficulties have at any time been made by any of the companies as to a thorough examination of all their works by the officers of the Local Government Board. It is hardly to be supposed that they would now adopt so unwise a course, but should they do so the President of the Local Government Board would not have the slightest difficulty in passing those further measures of control which have already been recommended by two Royal Commissions and which we think should be embodied in a Bill and passed without delay.

[1] THE LANCET, May 8th, 1897, p. 1292.

PLYMOUTH BOROUGH INFECTIOUS DISEASES HOSPITAL.—At the meeting of the Plymouth Borough Council held on Feb. 12th it was decided to enlarge the Borough Infectious Diseases Hospital at an estimated cost of £8512. At present the hospital contains only 32 beds; the additional accommodation will consist of two pavilions containing 10 and 22 beds respectively.

Annotations.

"Ne quid nimis."

THE ROYAL COMMISSION ON THE SOUTH AFRICAN HOSPITALS.

THE report of the Royal Commissioners upon the South African Hospitals appeared at that sad moment when all our thoughts were fixed upon the historic event taking place at Osborne House. The report did not, therefore, immediately receive the attention that was its due, but such attention will no longer be withheld from it. It is abundantly clear from the discussions which have taken place and which will continue to take place in both Houses of Parliament, and from the correspondence in many journals, that the public are awaking to the conclusion that the report is an exceedingly interesting document. Its importance may be gauged from the character of some of the criticism with which it has met. We begin this week to lay a full abstract of the report before our readers. Parts I. and II. of the report, which lend themselves to greater condensation than the remainder of the report, will be found on page 573 of the present issue, in abstract. The gist of Parts III. and IV., which will have to be published at greater length, will appear next week. We shall then proceed to deal with the report.

THE RELATION OF CRIMINALITY IN THE OFFSPRING TO ALCOHOLISM IN THE PARENTS.

DR. L. ROBINOVITCH, formerly assistant physician at the St. Anne Asylum, Paris, contributes to the December, 1900, number of the *Medico-Legal Journal* of New York a paper on the above subject and makes an attempt to trace the "extent to which alcoholism in the parent is responsible for that psycho-pathology in the offspring which manifests itself in criminality." The clinical material examined consisted of the histories of persons sequestrated in asylums and prisons. In order to avoid confusion, however, it was necessary to exclude from consideration those persons whose mental condition made them wholly irresponsible for their acts, such as those who had committed crimes under the influence of insane impulses and delusions in all their varieties, or who were the subject of organic mental derangements or chronic alcoholic insanity, or who exhibited symptoms of congenital mental and moral deficiency. In a word, those persons were excluded "whose vicious deeds were committed without intention or forethought of malice and intent." Thus of 50 criminals admitted to the St. Anne Asylum during the two years 1898 and 1899 and fulfilling the above conditions the clinical histories were characteristic, and the following may be quoted as a typical case. A man, 27 years of age, was the son of a drunkard. The father was addicted to the use of absinthe and was a man of abusive and violent disposition towards his wife, the latter being a woman of normal disposition and of good bodily health. There were seven other children of the marriage in addition to the patient. Of these, one, a girl, was feeble-minded and became the mother of an illegitimate child, one boy was timid and odd in conduct, while another boy and a girl were dull and incapable of earning a living. The patient's paternal aunt was melancholic and suffered from attacks of depression and crying, and his uncle was insane. His grandmother on the mother's side was markedly irritable and suffered from intense mental depression. The patient was born at full term, walked at the age of three years, and began to talk at the age of five. At the age of 16 he began to exhibit vicious propensities, frequented disreputable places, and was convicted of attempts at rape on young children. At the age of 18 he enlisted as a volunteer but was discharged afterwards for larceny. He took to drinking and was placed as a patient in an asylum, whence he escaped shortly after admission. "From that time on he continued gravitating from asylum to prison and back again." After every discharge he would commit a crime, be caught and sent again to prison. He was addicted to absinthe-drinking and suffered now and then from epileptiform attacks. He was, moreover, an expert simulator of these convulsions and had succeeded in deceiving physicians. He passed successively through the asylums of Villejuif, St. Anne, Ville Evrard, and Bicêtre as a patient and was detected in the practice of unnatural sexual crimes. When living outside he consorted with prostitutes on whom he depended for maintenance. He associated with thieves, and attempted murder, and was eventually placed in the St. Anne Asylum. Degenerate, depraved, with perversion of both instincts and moral sense, his life was one continuous manifestation of criminality and vice. He was arrested more than thirty times and his admissions to asylums were still more frequent. In a second case, that of a boy, aged 10 years, the son of an alcoholic father, the symptoms were excessive passion and temper, destructiveness, and attempts at arson, all manifested in childhood. He contracted vagrant habits when a boy and attempted to kill another boy, lying in wait for 12 days near the latter's residence. From a detailed statistical analysis of such histories Dr. Robinovitch concludes that in the vast majority of cases (over 90 per cent.) alcoholism existed only on the father's side. Of a total of 127 children 50 were fit for asylum or prison and formed the material for the present study, 40 died in infancy or prematurely, and 37 were living. Of the 37 living, 27 were in good physical condition. The rest suffered from meningitis (four cases), convulsions (three cases), or other forms of disease, and one of them was beginning to manifest criminal instincts.

THE MEDICAL OFFICER OF HEALTH AND THE PLAGUE AT HULL.

AT a meeting of the Hull Sanitary Committee held on Feb. 15th a gratifying communication was read from the Foreign Office stating that the foreign representatives in London of the parties to the Venice Convention had been notified that the plague at Hull had now ceased. Mr. W. Holder said that he thought that the fact of the prompt stamping out of the plague, the saving of probably hundreds of lives, and the conserving of the trade of the port should not be allowed to pass without the committee marking in some way their appreciation of the energy and services rendered by the medical officer of health, Dr. John Wright Mason. Dr. Mason of recent years had had to meet in behalf of the city of Hull assaults of cholera, small-pox, and plague, and he considered that Hull was deeply indebted to him. A sub-committee was appointed to consider what form the testimonial should take. We congratulate Dr. Mason most warmly both upon the success which has attended his efforts to arrest the plague and also upon the fact that his services are duly recognised by those whom he serves —a state of matters which is not so common as it should be. The post of a port medical officer of health is nowadays singularly arduous and responsible. Owing to the facilities which modern invention gives for intercommunication among the nations the march of epidemic diseases is infinitely more rapid than it used to be. For us in these islands infection is always at our doors. The "shuttles of an empire's loom" weave their web across every sea and ocean, and there is always the chance that plague, yellow fever, or cholera may accompany their course. Coincidently with Hull being

declared free from plague a Peninsular and Oriental mail-steamer came into Plymouth reporting that one of her crew had died from plague before the vessel left Bombay. No fresh cases had occurred, but all the passengers and crew were carefully inspected and the names and addresses of those who wished to disembark were recorded. So the work goes on—attack and repulse follow one another all round the coast; therefore let us remember with gratitude the unwearying watchfulness of our port medical officers.

THE CASE OF HENRY DAVIS.

ON Feb. 15th, Henry Davis of 309, Portobello-road and 25, Oxford-gardens, was convicted on a summons charging him with wilfully and falsely pretending to be and using the title of "Doctor," thereby implying that he was a registered medical practitioner. Mr. Curtis-Bennett, a London magistrate of long experience, according to the report before us described the case as the worst he had ever had before him and fined Davis £20 with 10 guineas costs. The nature of "Dr. Davis's" business had been fully explained to the learned magistrate; his excuse for using the title "Doctor" was said by his counsel to be a diploma from Berne University, but the exposure of his methods by the prosecution somewhat discounted the value of this statement. A bottle of sham "medicine," for instance, sold by Davis as of special virtue for 17*s*. was practically the same as another sold by him for 4*s*., while full explanation was given of his traffic in "pills a boon to womankind." "Dr. Davis" is one of the oldest and most constant advertisers of these pills. In our series of articles on Quacks and Abortion we dealt with his goods in detail[1] giving their analysis. This certainly did not prove them to be effective abortifacients, but the literature which accompanied them showed that they were sold, and likely to be taken, as such. They were "Famous female pills," "the most effective in the world." There was the usual indication of the character claimed for them supplied by the warning that they were not to be taken by those expecting to become mothers, and on the same sheet of paper was the advertisement of a book invaluable for women, entitled, "How to Limit your Family and Woman her Complaints." While to some extent the business of Henry Davis may suffer by his being obliged to drop the title "Doctor," and while the proceedings taken may to some extent act as a deterrent to him, it seems to us a matter of regret that such a trade as his should be permitted to continue without more direct interference by the police. No one can accuse him of concealment. Mr. Curtis-Bennett seems to have said that happily advertisements such as those which had been referred to before him were now refused by most of the newspapers. The particular newspaper to which reference was made before Mr. Curtis-Bennett as giving publicity to the trade of "Dr. Davis's Famous Pills," "a boon to womankind," was the *People*. In a recent issue of the *People* the advertisement of Davis does not stand alone. We note on another page that of Martin who offers "Ladies' apiol and steel pills, a remedy for all irregularities, superseding bitter apple, pill cochia, pennyroyal, &c." These advertisements appear to us to be tolerably plainly worded and to indicate without much concealment the nature of the goods offered by the advertisers. We dealt, however, with Martin's pills, as well as with those of Davis, in the issue of THE LANCET referred to above and our articles were forwarded to the newspapers which we then named as containing objectionable advertisements. We have always expressed the belief that these advertisements had only disappeared for a time and that they would gradually be seen again, and their reappearance in the *People* confirms our view. Perhaps, however, the attention of its proprietor or proprietors may not have been called to the matter. We are strongly of opinion that it is one worthy of the notice of all newspaper proprietors who are concerned with their personal honour as well as with the honour of the newspaper press.

[1] THE LANCET, Dec. 31st, 1898, p. 1808.

"PURE BEER."

THE "Pure Beer" party were lucky in the ballot on Monday, for Mr. Purvis, the Member for Peterborough, who takes a keen interest in the movement, secured the fourth place. A Bill was accordingly read for the first time on Tuesday dealing with the subject on the lines of the Bill brought in by Sir Cuthbert Quilter in 1886. Recent events have certainly increased the chances of the movement, but we still regard them as very slender.

MEDICAL REPORTS OF THE CHINESE MARITIME CUSTOMS.

THE medical reports of the Chinese Maritime Customs for the half-year ended March 31st, 1900, published in London by Messrs. P. S. King and Son, consist of articles by Dr. O. F. Hall, Chungking; Dr. J. A. Lynch, Chinkiang; Dr. W. H. Park, Soochow; Dr. H. J. Hickin, Ningpo; Dr. H. M. McCandliss, Hoihow and Kiungchow; and Mr. A. S. Deane, Pakhoi. All these gentlemen describe the health of the foreign residents in their respective towns as satisfactory. Dr. Hall says that in Chungking "opium-smoking is very common and many women as well as men are enslaved to the habit. Its effects are bad beyond description, yet vary greatly in different cases." Among some portraits of patients appended to his report is one of a woman who, he says, "is 77 years old and has used opium daily for 47 years; she began for pleasure and has never been sick in any way; she shows no symptoms of debility from opium poison. She has broken off the habit and remains cured." Dr. Park mentions that he had recently used for impacted fæces "an injection of peroxide of hydrogen and the effect was all that could be desired." Dr. Hickin describes a case of malarial colic which lasted from the middle of September, 1899, to the end of January, 1900, and was then speedily removed by a few doses of quinine.

DECREASE OF GENERAL PARALYSIS IN ENGLAND AND WALES.

DR. R. S. STEWART of the Glamorgan County Council has furnished an interesting paper in the January number of the *Journal of Mental Science* dealing with the statistical records of the Commissioners in Lunacy with reference to the prevalence of general paralysis. In their fifty-third report the Commissioners conclude that general paralysis is "not increasing among the general population." Dr. Stewart compares the two halves of the decade 1888–97 and tabulates them as follows in order to show the percentages of general paralysis in patients admitted to asylums:—

Years.	Males.	Females.	Total.
1888-92	14·7	3·4	8·9
1893-97	13·1	2·8	7·8

The conclusion is that the diminution in general paralysis affects both males and females. In only one class of society is there an exception to this, and that is the one which provides the private male general paralytic. "The proportion in this class continues to increase, though at a slightly diminishing rate, until now it has arrived at that point that the proportion of private male general paralytics overtops that for male pauper patients. The steady progressive decline of general paralysis among private female patients ..... is continued and unless some material change takes place ..... the disease will apparently be extinct in half a century from the present." All age-periods are not affected

alike in the general decrease which has taken place. The greatest decrease takes place at the age-period of 45–54 years of age, whereas if regard be had to general paralysis in youths and young adults there is an actual increase. Different counties show different results, increase being shown in the industrial and coal-mining counties and decrease in rural districts.

BRITISH MEDICAL BENEVOLENT FUND.

THE annual meeting of subscribers to the British Medical Benevolent Fund was held at 84, Brook-street, W., on Feb. 12th, the President, Sir William Broadbent, Bart., being in the chair. The treasurer's financial statement for 1900 and the report of the committee were presented and they recorded steady and satisfactory progress. In the annuity department the capital has been increased by the purchase of £1600 Paisley Corporation 3 per cent. stock. The income from investments, all of which are in securities authorised by the Trustee Acts, amounted to £2355 13*s.* 3*d.*, of which £2213 6*s.* 8*d.* were paid away in annuities. During the year 16 vacancies were caused by death and they were promptly filled from the reserve list. The annuitants now number 111. In the grant department the subscriptions amounted to £1110 9*s.* 2*d.* and the donations to £773 7*s.* 6*d.* These figures are an increase upon those for 1899 but in the case of the donations the difference is due to two special gifts of 200 guineas and 100 guineas respectively. The grants made amounted to £1549, which sum was distributed to 165 cases in sums varying from £5 to £20. The accounts have been as usual subject to a searching investigation by a chartered accountant who in his report draws attention to the smallness of the working expenses, which were again less than 5 per cent. Hearty votes of thanks were passed to the President and to the treasurer, Dr. S. West, who with the remaining officers were unanimously re-elected. As in former years many distressing and well-recommended cases have had to be passed over in favour of still more urgent ones, and where aid has been given the sum granted has often been miserably inadequate, though all the Fund could afford. The applications reveal a depth of poverty which few can realise and which probably none suspect until the facts are put before them. The committee earnestly and confidently appeal to the profession to make the work of the fund and its claims for increased support more widely known.

THE PROPHYLAXIS OF MALARIA IN THE ITALIAN NAVY.

THE *Annali di Medicina Navale* for January, which, out of sympathy with our great national loss, is published with a black border, contains an important contribution on the Prophylaxis of Malaria by Dr. R. Procaccini of the Italian navy. It is illustrated by five maps and a graphic picture representing a detachment of investigators slumbering peacefully *al fresco* in low iron-strutted hammocks with their heads enveloped in bags and all other parts that are vulnerable to the anopheles and its congeners protected in a similar way. The article in the first place contains a brief but clear account of the present state of our knowledge regarding the nature of malaria and the best means of warding off its assaults. This ground has now been gone over a good many times, but the author's patriotism must excuse him. England and Italy, exclaims the author in his exordium, were the first among the nations to take an interest in the great question, but after a brief interval their good example was followed by Germany, next by France, and finally by Belgium. In the second place Dr. Procaccini relates the history of some experiments which were carried out by an expedition under Government auspices in one of the most malarious districts of the kingdom. The locality selected consisted of the extreme north of Sardinia, together with the islands of Maddalena and Caprera, the last named, it is scarcely necessary to say, having been the home of Garibaldi. The details of the story are full of interest. The expedition was sent out with special reference to prophylactic measures in the naval and military services. Out of 104 men forming the expedition 103 escaped malaria entirely. The 104th man was attacked, but it was ascertained on inquiry that he was in the habit of displacing his protective mask at night in order to smoke. If a mask is a *sine quâ non* a difficulty in this connexion at once arises with sentries, whose vision naturally should be as unobstructed as possible, but who require protection from malaria as much as the rest of the forces of war. Dr. Procaccini observes, "where there's a will there's a way," but the means to overcome this objection will take some finding. Serious difficulty in carrying out prophylactic measures in the services, both in Italy and in other countries, lies in the fact that soldiers and sailors are hardly made to understand the value of hygienic precautions. There is room for hope that as education advances this source of trouble will be eliminated.

THE BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION.

IT will be remembered[1] that the General Medical Council at its last session in November, 1900, had before it the case of Dr. Henry Ward Irvine, the consultant to the Birmingham Consultative Medical and Surgical Institution. The Council came to the conclusion that the charges against Dr. Irvine of advertising were proved, but gave him until May, 1901, to reconsider his position. This action seems to have vexed the committee of the Consultative Institution, and a largely attended meeting was held on Feb. 13th to consider the action of the Council. Mr. Arthur Chamberlain was in the chair. Mr. Councillor Nettlefold rose to propose a motion of confidence in the institution, a motion which had been drafted by the committee. In the course of his speech he remarked that if the institution were not in existence the class of people for whom it was called into existence would have one of three courses open to them. They would have to go to a "street doctor," to the hospitals, or to a consulting physician who would charge very high fees. If Dr. Irvine was struck off the roll of his profession what did it matter to them? He would not be able to sue for fees, but they were business men and they got their fees in advance. He would not be able to sign death certificates, but they did not intend him to kill his patients. After other members had spoken Mr. Arthur Chamberlain addressed the meeting and in the course of his speech said that if the General Medical Council at the meeting in May should think that they were justified in depriving a fellow-practitioner of his means of living, the feeling of that committee would be to appeal to a High Court of Justice. With regard to the admission of persons to the benefits of the institution there should be no tests whatever, and even if all the consultants in the city agreed to make concessions with regard to fees to poor people, it would be wise for working men to have some arrangement of their own. The motion, which ran as follows, was carried with enthusiasm:—

"That this meeting is of opinion that the scheme of the Consultative Medical and Surgical Institution, Birmingham, for providing facilities for obtaining the advice and opinion of properly qualified physicians and surgeons at a fee within the means of people of limited income is of great advantage to the class affected, is calculated to materially reduce the abuse of hospital charity, and as it cannot possibly be an injury to anyone does not justify the opposition and abuse

[1] THE LANCET, Dec. 8th, 1900, p. 1688.

with which it has been met by certain members of the medical profession. This meeting accordingly requests the managers of the movement to proceed with their work and assures them of its continued confidence and support."

The committee is evidently very angry with the General Medical Council and with the Birmingham medical practitioners. Mr. Councillor Nettlefold's remarks are simply silly. He seems to imagine that no patients of a medical man die unless the medical man kills them; and as for his asking "what will it matter if Dr. Irvine is struck off the roll," he will find it will matter a great deal both to the Consultative Institution and to Dr. Irvine, who will be ill-advised to run contrary to the views of the highest tribunal of the medical profession and to the general opinion of his professional brethren. With regard to the advertisement cards which formed the basis of the complaint laid before the General Medical Council, Mr. Councillor Nettlefold, writing to the *Birmingham Daily Mail* of Feb. 15th, says that the committee have done their best to withdraw them. This is as it should be, but the system of the institution is, as we have pointed out previously, the chief matter for condemnation.

TRAFFIC IN CHILDREN.

THE dangers which beset the lives of infants who are made the subject of baby-farming are frequently and forcibly brought home to medical men practising among the poor, and it is useful to them to be aware of the law upon the subject. In one particular they are directly concerned in its enforcement, for under the Infant Life Protection Act of 1897, in the case of the death of an infant in the custody of a baby-farmer working under the Act, the medical man has to decide by withholding or giving his certificate whether an inquest shall or shall not take place. Should he refuse the certificate the coroner has no discretion but to hold the inquest. A case recently brought before a London magistrate, under another portion of the statute referred to, is an illustration of how, although passed with the best intentions, an Act of Parliament may to a great extent be unwieldy and ineffective in practice. A woman named Herbert had received a lump sum of £20 to take charge of an infant until it should be old enough to take care of itself, and had adopted the rather obvious, if dishonest, course of sub-farming the child, presumably for a small weekly sum, to an old woman, in whose custody it was suffering considerably from neglect. The fifth section of the Infant Life Protection Act provides that a person thus taking a lump sum for the bringing up of an infant under two years of age, if it be a sum not exceeding £20, shall give notice to the local authority in order that the future upbringing of the child may be subject to inspection. Herbert had not given this notice and so was summoned under the section referred to. Her first answer was that she had been paid £24 for taking the child, and had she been able to prove this, or indeed that she had taken £20 0*s.* 1*d.*, she would have been safe from the Act, which limits its protection, as we have stated, to children for whose rearing a sum not exceeding £20 is paid. She could not, however, establish this defence and so she was convicted, upon which there followed the question of how she was to be punished. The Act apparently only provides for the forfeiting of the money received in such a case, and Herbert had none of it left so she could not pay forfeit. The magistrate doubted whether, as there was no provision in the Act for this contingency, he could order imprisonment as an alternative for the money payment, and it looked as if there would be no possibility of inflicting any penalty at all. It happened, however, that in obtaining the child Herbert had produced a testimonial to her own merits which she had herself written, and she was charged with obtaining money by false pretences, pleaded guilty, and was sent to prison. This was, no doubt, a desirable termination to the case. But if a woman, who for a time had looked after the child for 5*s.* 6*d.* a week and had grown fond of it, had not informed an inspector of the county council of its removal from her care, and if the inspector had not been active in tracing it, Herbert might have realised a substantial profit on her deal owing to the premature death of the infant. Again, having been detected and her method of doing business exposed, she came near to escaping without punishment, while she was not eventually punished under the Infant Life Protection Act at all. Perhaps those who framed the Act intended that those who trangress it by not giving notice of their transactions under the fifth section of it should be punished by fine or imprisonment, as for an offence under the Act, and should not only be ordered to forfeit the sum received by them. The learned magistrate, however, does not seem to have taken this view, and certainly the section ordering the forfeiture of the money paid does not allude to the imposition of any other punishment as well.

SANITATION AT STEVENAGE.

THE life of a medical officer of health of a small district is not altogether an easy one. In the pursuance of his duties he is almost sure to come into contact with conflicting interests. If he is allowed to be in private practice as well as to hold his post of medical officer of health he not infrequently may be compelled to run counter to his brother practitioners; but perhaps his position is most difficult when he has to point out to the members of the urban or rural sanitary council, whose servant he technically is, sanitary defects in their property. Such a case has arisen at Stevenage, as instanced in the report of Dr. R. A. Dunn, the medical officer of health of the Stevenage Urban District, a report which has been commented upon in an open letter to the ratepayers published in the *Hertfordshire Express* of Feb. 15th. The passage in the report, a copy of which lies before us, to which allusion is made is as follows:—

"On looking through the inspector's journal I notice that he has made upwards of a hundred visits. As a result of these he brought to your notice some 28 pit or pail closets, only a few of which have been done away with; seven cases in which house property was not connected with the sewer; in most of these cases the work has been done, but in two cases, both, I am sorry to say, the property of members of your council, for a very long time our complaints were without avail, although the statutory notices were served. In one of these the work has not even yet been done. Let me point out the extremely bad effect this has in carrying out necessary improvements. Defaulters who are well aware of these and similar cases have more than once said to me: 'If we were only on the council we should not be compelled to do this.' Such a state of affairs brings your authority into contempt and acts as a grave obstacle to any reform."

This is undoubtedly a very grave state of matters and we certainly hope that the ratepayers will see to it in future that only men are elected on the council who will do their duty to their neighbour even if it be to their own hindrance. Dr. Dunn has, we think, put his finger upon the most harmful result which such jobbery on the part of the council brings about—namely, that other defaulters shelter themselves behind the evil deeds of defaulting councillors. Dr. Dunn also points out that his report and that of the sanitary inspector upon house connexions and that upon dairies and milkshops have received practically no attention from the council whatever. Well may he add that "this apparent apathy on the part of the council tends to cause its officers to lose that keenness and interest in their work which it is so important for them to have." We trust that before the next election of councillors those in fault will have seen the error of their ways and that the ratepayers will take

note of Dr. Dunn's remarks. In the meantime we congratulate him upon the stand which he has made for the purity of municipal life.

THE BEER-POISONING EPIDEMIC.

THE medical officer of health of Manchester, Dr. James Niven, has presented a report upon the outbreak of arsenical poisoning, a copy of which we have recently received. It deals exhaustively with the many aspects of the outbreak. Dr. Niven suggests that the recent occurrence does not stand quite alone and that previous mischief in connexion with alcohol has occurred in an epidemic fashion. It is possible that there may have been arsenic present in the beer formerly. There is, indeed, reason to suspect, according to Dr. Niven, that the same phenomena may have been going on for years, though in a slighter degree. This, he adds, would justify some delay in recognising the nature of the disease, since the cases would be regarded as ordinary alcoholic cases of a recognised type, with an unusual proportion of certain striking though not unknown features. We are glad that some stress is made in the report upon the advisability of instituting quantitative analyses. There is a slip in the report on p. 21 where in describing Marsh's test it is stated that the hydrogen evolved is passed through chloride of lime to dry it. Chloride of calcium is, of course, meant, as bleaching powder would most probably destroy arseniuretted hydrogen.

THE COMMUNICABILITY OF GLANDERS.

WE announced last week that the President of the Board of Agriculture has appointed a committee to conduct experimental investigations into the communicability of glanders. An official inquiry into the subject cannot be otherwise than beneficial to practitioners, both medical and veterinary, and particularly to those who make a special study of public health. Glanders is one of the most terrible of all the diseases which can be transmitted from animals to man, and every year instances occur in which human beings become infected from contact with glandered horses. Only a few days ago there was an illustration of this in the Fulham coroner's court, when an inquest was held on the body of a man who had died from the disease. The exact date and source of the infection were not ascertained, as the deceased was an erratic worker, but his occupation was that of a groom or odd man about cab- and omnibus-yards—work that continually brought him into contact with horses and harness. It is well known that glanders exists principally in London, Liverpool, and Glasgow, and that stables belonging to cabmen are those in which the disease is most frequently detected. The conditions under which the majority of cab-horses live are especially favourable for its spread; hygienic arrangements are often almost absent, the horses are crowded together in a totally inadequate amount of cubic space, and the manger is usually a long trough with no divisions in it to keep the food given to one horse apart from that of his fellow. Even if the divisions are provided they are so close that a horse has only to stretch out his neck in order to put his nose into his neighbour's share. As a rule, too, the horses drink out of one tank. This habit cannot be too much condemned; it is even questionable whether the street drinking fountains do not often do more harm than good by disseminating glanderous material. At almost any time of year, but particularly in the summer, nasal mucus can be seen floating on the surface of the water in these drinking troughs and at any time this may be from the nostril of a glandered animal. The stationary tap and bucket system affords much more safety. Since the discovery of mallein the authorities have had on their hands an almost infallible means whereby glanders can be detected. As a diagnostic agent its properties leave nothing to be desired. The committee which has just been appointed will inquire into the influence of this agent to check or cure the disease. Many experiments have been made in Great Britain and abroad to test this question, which was first raised by M. Nocard, but almost the whole of the evidence has gone to prove that as a curative agent mallein is of no value. It is true that many horses will refuse to react when tested again and again, but it is also well known now that glanders is by no means absolutely bound to run a rapid and fatal course in the horse, and cases of recovery without any treatment at all are not uncommon. In making equine post-mortem examinations in London the veterinary practitioner frequently finds old-standing lesions of glanders which have been spontaneously cured, a fact which has been confirmed by microscopical and other tests. Under strict veterinary inspection at regular intervals it would be quite possible to stamp out glanders completely in England. If when a case was reported in a stable the whole of the animals in that stable or stud were subjected to the mallein test and those that reacted were isolated from the healthy there is no reason why they should not do useful work again. It would be necessary to test them again and again and upon the slightest clinical manifestation to insist upon slaughter at once. Many would completely recover. On no account should the animals be sold or lost sight of. The immediate slaughter of all the reacting ones would, of course, settle the case at once and thus end all fear of contagion from them, but the question of compensation would here have to come in and the cost of such a scheme would necessarily be great. Possibly the new committee may be able to bring forward a scheme which will satisfy everybody. At any rate a most valuable report should result, for the names of those appointed upon the committee show that it will include observers who have had unique opportunities for testing their views.

PROTECTIVE INOCULATION AND SERUM-THERAPY.

IN another column we publish a paper read before the North London Medical Society by Dr. F. L. Bunch on the above subject. Although the paper contains nothing very new it forms an admirable *résumé* of our present knowledge on a difficult subject. The majority of practitioners have neither time nor opportunity to study elaborate records of research works and will welcome such a concise presentment of the *status quo* as is given in this paper. Immunity is a condition which has only comparatively recently been investigated. Several theories have been advanced to attempt to explain the forces acting within the body which tend to produce the required resistance to disease. Some of these forces are natural; others are acquired or artificially introduced into the organism. The chief of these theories Dr. Bunch explains and criticises. The methods employed in attenuating cultures are also described. The bitter disappointment to which tuberculin gave rise is commented on, and the attempt to bring about satisfactory protective inoculation in connexion with typhoid fever receives due attention. Here, like other pathologists, Dr. Bunch is forced to conclude that further statistics are necessary before any definite conclusions can be arrived at. To the practitioner the question of cure or arrest of an already developed infectious disease, will probably have the greatest interest. The investigations of Behring, Kitasato, and Sidney Martin in the serum-therapeutics of diphtheria are briefly described. Dr. Bunch lays stress on one point which has hitherto not received the attention it

merits—namely, that antitoxin serum has no reparative action. It cannot regenerate cells which have already undergone katabolic pathological changes, and, further, a certain amount of antitoxin can only neutralise a certain amount of toxin. It follows from this that it is necessary to commence the treatment at the earliest possible moment, when there is a minimum amount of toxin already in the circulation, and we agree with Dr. Bunch that, seeing how innocuous its employment is, a large dose of serum should be given at the earliest possible moment in every case of diphtheria. Some authorities, especially in the United States, recommend that all patients suffering from suspicious sore-throats should receive a full dose of the antitoxin. We do not go quite so far as this, but undoubtedly valuable time is often lost in suspicious cases waiting for a bacteriological diagnosis which may then be only a doubtful one, the toxin meanwhile increasing in the body and the prognosis in a similar ratio becoming more grave.

RINGWORM IN WORKHOUSE SCHOOLS.

THE Metropolitan Asylums Board has made a new departure in the arrangements for the treatment of cases of ringworm under the care of the metropolitan boards of guardians. The Asylums Board has opened at Witham, in Essex, a building which will accommodate 180 children suffering from ringworm. During their stay in the school the children will receive education just as if they were healthy children in an ordinary Poor-law school. The school was opened on Feb. 12th, and Dr. T. Colcott Fox has been appointed to make arrangements for the treatment of the cases. The results of the treatment of ringworm amongst children in workhouses are so unsatisfactory that this new plan deserves to be welcomed, especially as the Metropolitan Asylums Board has appointed a dermatologist to superintend the treatment who has done a great amount of original work on the fungi of ringworm. We understand that this school is merely temporary, but if it proves successful we have no doubt that it will be continued so long as it is needed. That the children under this arrangement do not have to miss their school training is an additional argument in favour of the judicious action of the Metropolitan Asylums Board.

A NEW TEST FOR MASTOIDITIS.

IN the *Journal of the American Medical Association* of Jan. 26th Dr. A. H. Andrews has described a new test for mastoiditis, which is performed by placing a vibrating tuning-fork over the antrum and listening to the sound over the tip of the mastoid with a small belled stethoscope. If the mastoid is filled with pus or granulations, or dense from obliteration of the air-cells, the sound is louder than on the opposite mastoid. Care must be taken not to stretch the skin between the stethoscope and the tuning-fork, for this increases the audibility of the sound. In 40 patients without mastoid symptoms Dr. Andrews has found no perceptible difference between the two sides; in four cases of mastoid disease the sound was louder on the affected side. The following case is an example. A woman, aged 40 years, had had suppurative disease of the left ear with occasional attacks of acute pain for 15 years. During three weeks she had suffered from a dull pain in the ear and mastoid region, which sometimes extended over the side of the head and as far forwards as the eye. The membrana tympani had almost disappeared and the ossicles could not be seen. A cholesteatomatous mass occupied the attic and the upper part of the middle ear. When portions of this mass were removed the surface beneath was found covered with normal granulations. The temperature varied between normal and 101°F. Deep pressure over the mastoid was painful. When the bell of the stethoscope was placed on the tip of the mastoid with the handle of the tuning-fork over the antrum the sound was much louder than on the right side: on the left side the fork was heard for 30 seconds, on the right for 16. The usual post-auricular incision was made and the mastoid cortex was found to be of ordinary density. The air-cells were small and filled with granulations. The cavity was cleared of diseased tissue, the posterior wall of the auditory canal and the outer wall of the attic were chiselled away, and the granulations and cholesteatoma were removed from the attic. The facial nerve was found exposed above the fenestra ovalis and sponging the cavity caused spasm of the left eyelid and side of the face. The fork which Dr. Andrews uses for this test is C 512, so constructed that it can be heard by the normal ear for about 35 seconds.

THE BACTERIOLOGY OF YELLOW FEVER.

THE Liverpool School of Tropical Medicine is to be congratulated on the encouragement which it has given to original research, the benefits accruing from which may be of incalculable value to mankind. The work performed by the Malaria Commission is well known, and we now publish an abstract of an interim report on yellow fever by the Yellow Fever Commission of the School. The report bears the names of Dr. Herbert E. Durham and the late Dr. Walter Myers. The completion of the report, of which this is an abstract, was unfortunately interrupted by the onset of attacks of yellow fever in both of the investigators and the lamentable death of Dr. Myers; it was therefore deemed advisable to submit for the time being for publication a shortened report only. Several micro-organisms have been credited with a causal relationship to yellow fever, but none of these has been generally recognised as satisfying all the requirements of a pathogenic organism. Dr. Durham and Dr. Myers describe a fine small bacillus which they found in all the fatal cases of yellow fever which they examined. They consider it probable that this same bacillus has been met with, but not recognised, by three other observers. They likewise consider that it is probable that recognition has not been previously accorded to this bacillus by reason of the reluctance with which it takes up stains and establishes growths in artificial media. These laboratory difficulties, however, were overcome by the two observers. Search was made for parasites of the nature of protozoa, but it was concluded that yellow fever is not due to this class of parasite. The report considers that the evidence in favour of the etiological importance of the fine small bacillus is stronger than any that has yet been adduced for any other "yellow fever germ." The abstract is too brief for us to form any decisive judgment upon the work, but we await the full report of the brave and able investigators with interest.

AS all our readers know, the metropolitan water companies propose to enforce new regulations with regard to water-fittings, and an inquiry has been instituted into the matter by the Local Government Board, who have appointed Mr. Perrin, their water examiner, Dr. Theodore Thomson, one of the medical inspectors, and Mr. E. A. Fawcett, to make a report on the matter. With one aspect of the new regulations we dealt last week. The present time, in our opinion, is not opportune for any alteration in the regulations of the metropolitan water companies. Efficient control over the companies is more strongly indicated than is control over the metropolitan water consumers by the companies. We feel sure that the representatives of the metropolitan boroughs will take this

view at the inquiry, but unfortunately the cost to the ratepayers for the payment of counsel must necessarily be considerable.

SIR WILLIAM MITCHELL BANKS will deliver the Second Hunterian Lecture of the Hunterian Society on Wednesday, Feb. 27th, 8.30 P.M., at the London Institution, Finsbury-circus, E.C. Subject, the Neglect of the Actual Cautery in Surgery and its Value in the Treatment of Pruritus Ani. All members of the medical profession are cordially invited.

SEVERAL important committees of the General Medical Council are summoned to meet next week. The Executive Committee will meet on Monday, Feb. 25th, at 1.30 P.M., and the Penal Cases Committee on the same day at 4 P.M. The Dental Committee will meet on Tuesday, Feb. 26th.

Miss Lillie Emma Vahine-é-tua Saville, L.S.A. Lond., M.D. Brux., of the London Mission, has received from the King the decoration of the Royal Red Cross in recognition of services at the International Hospital during the siege of the Legations at Pekin.

A CONFERENCE of representatives of the medical profession and of certain friendly societies has been held at the offices of the British Medical Association. The medical representatives maintained the view that wage-limits should be enforced.

THE lecturers and honorary staff of the Dental Hospital of London have generously contributed a special donation of £2000 towards the building of the new hospital in Leicester-square, which is now nearing completion.

SIR HUGH REEVE BEEVOR, Bart., M.D., F.R.C.P., L.S.A. Lond., has been re-elected the representative of the Society of Apothecaries of London on the General Medical Council for one year from Feb. 6th.

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms of the Hôtel Métropole on Friday, March 8th, at 7.30 P.M.

SIR JAMES REID, Bart., K.C.B., Physician to Her late Majesty the Queen, has been appointed a Knight Grand Cross of the Royal Victorian Order.

ABSTRACT OF AN INTERIM REPORT[1] ON YELLOW FEVER, BY THE YELLOW FEVER COMMISSION OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

BY HERBERT E. DURHAM, M.B., B.C. CANTAB., F.R.C.S. ENG.,

AND

THE LATE WALTER MYERS, B.SC. LOND., M.B., B.C. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.

1. SUFFICIENT search reveals the presence of a fine small bacillus in the organs of all fatal cases of yellow fever. We have found it in each of the 14 cadavers examined for the purpose. In diameter the bacillus somewhat recalls that of the influenza bacillus; seen in the tissues it is about 4 μ in length.

2. This bacillus has been found in kidney, in spleen, in mesenteric, portal, and axillary[2] lymphatic glands, &c., taken from yellow fever cadavers directly after death. In the contents of the lower intestine apparently the same bacillus is found often in extraordinary preponderance over other micro-organisms. Preparations of the pieces of "mucus," which are usually, if not always, present in yellow fever stools, at times may almost present the appearance of "pure culture."

3. Preparations of the organs usually fail to show the presence of any other bacteria, the absence of which is confirmed by the usual sterility of cultivation experiments.

4. It is probable that this same bacillus has been met with, but not recognised, by three other observers. Dr. Sternberg[3] has mentioned it; and he has also recorded the finding of similar organisms in material derived from Dr. Domingos Freire and Dr. Carmona y Valle, but he did not recognise its presence frequently, probably on account of the employment of insufficiently stringent staining technique.

5. It is probable that recognition has not been previously accorded to this bacillus by reason of the difficulty with which it takes up stains (especially methylene blue) and by reason of the difficulty of establishing growths on artificial media.

6. The most successful staining reagent is carbolic fuchsin solution (Ziehl) diluted with 5 per cent. phenol solution (to prevent accidental contamination during the long staining period), immersion for several hours, followed by differentiation in weak acetic acid. Two hours' staining period may fail to reveal bacilli which appear after from 12 to 18 hours. The bacilli in the stools are often of greater length than are those in the tissues and they may stain rather more easily; naturally the same is true of cultures.

7. Since the bacilli are small and comparatively few in numbers they are difficult to find. To facilitate matters at our last two necropsies (the fourteenth and fifteenth) a method of sedimentation has been adopted. A considerable quantity of organ juice is emulsified with antiseptic solutions, minute precautions against contamination and for control being taken; the emulsion is shaken from time to time and allowed to settle. The method is successful and may form a steady means of preserving bacteria containing material for future study. The best fluid for the purpose has yet to be worked out; hitherto normal saline with about $\frac{1}{2}$ per cent. sublimate has been employed.

8. Pure growths of these bacilli are not obtained in ordinary aerobic and anaerobic culture tubes.

9. Some pure cultures have been obtained by placing whole mesenteric glands (cut out by means of the thermo-cautery) into broth under strict hydrogen atmosphere. Investigations into the necessary constitution of culture media for successful cultivation is in progress.

10. Much search was made for parasites of the nature of protozoa. We conclude that yellow fever is not due to this class of parasite. Our examinations were made on very fresh organ juice blood, &c., taken at various stages of the disease, with and without centrifugalisation[4] and on specimens fixed and stained in appropriate ways. We may add that we have sometimes examined the organs in a fresh state under the microscope within half an hour after death.

11. The endeavour to prove a man-to-man transference of yellow fever by means of a particular kind of gnat by the recent American Commission is hardly intelligible for bacillary disease. Moreover, it does not seem to be borne out by their experiments, nor does it appear to satisfy certain endemiological conditions. It is proposed to deal more fully with the endemiology and epidemiology of the disease on a later occasion.

12. We think that the evidence in favour of the etiological importance of the fine small bacillus is stronger than any that has yet been adduced for any other pretended "yellow fever germ." At the same time there is a much further work to be done ere its final establishment can be claimed. The acquisition of a new intestinal bacterium would explain the immunity of the "acclimatised."

Para, Brazil.

[1] The completion of the interim report of which this is an abstract was interrupted by the onset of attacks of yellow fever in both of us. The loss of my much lamented colleague renders it advisable to submit this shortened report only, for the time being.

[2] We find these constantly enlarged and much injected, though whether this is specific we are not able to say.

[3] Report on Etiology and Prevention of Yellow Fever, 1890.

[4] We have found this sometimes useful in examining the blood of ague patients.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

I.

WE have already in our issue of Feb. 2nd, p. 349, given a brief *résumé* of the report of the Commissioners and we now proceed to consider the report in detail. Passing over Part I. of the Report, which contains a brief account of the proceedings by which the Commissioners were enabled to discharge their duties, together with some observations upon the evidence and the work done, we come to Part II., which deals with particulars of complaints made as to the treatment of the sick and wounded and certain conclusions arrived at by the Commissioners of a general character. Firstly comes the question of

THE INSUFFICIENCY OF THE ROYAL ARMY MEDICAL CORPS.

The Commissioners say:—

The military and medical authorities certainly never anticipated when this war became probable that it would be of the magnitude it has since attained. The Royal Army Medical Corps was wholly insufficient in staff and equipment for such a war, and it was not so constituted as to have means provided by which its staff could be very materially enlarged, or its deficiencies promptly made good. These deficiencies were felt throughout the South African campaign, as will more clearly appear when we deal in detail (in Part III.) with the complaints which have been made in respect of the care of the sick and wounded.

The deficiency in the staff of the Royal Army Medical Corps before this war was not the fault of the Director-General and the staff of officers associated with him. They had for a considerable time before the outbreak urged upon the military authorities the necessity for an increase of the corps, but for the most part without avail.

The Commissioners proceed to give an account of "unit allowances," or the ordinary provisions for the care of the sick and wounded of an army on active service at the front:—

One medical officer is allotted to each regiment and to each brigade of artillery. He accompanies his regiment and carries with him on service his medicines and medical and surgical appliances. These regimental medical officers are not now, as was once the case, attached in times of peace to particular regiments; the result being that when war commences the medical officers are not personally acquainted with the men of the regiments to which they are attached. The question whether this ought to be remedied to any extent, and if so in what manner, should, we think, be made one of the subjects of inquiry when this war is ended.

In mentioning field hospitals they say that numerous complaints arose from the fact that under certain circumstances field hospitals had to be largely used as fixed hospitals. The ambulance wagons supplied to the bearer companies are, in the opinion of the Commissioners, heavy, jolty, and uncomfortable. The type in use, they think, could be and should be improved.

STATIONARY AND GENERAL HOSPITALS.

With regard to these hospitals the Commissioners point out that the type of marquee in use should be improved. This, they say, is a matter for military experts. The Commissioners also note that as fixed hospitals are not generally furnished with their own transport delay often occurs in removing patients from railway or other stations to the hospital. They consider that the use of bearer ambulances should be largely extended.

NURSES.

As to nurses, by which term is meant female nurses, the Commissioners consider that their use should be largely extended and that they certainly ought to be employed for enteric and other fever patients. The objection taken to the employment of local nurses was not well founded.

DEFICIENCY IN THE STAFF AND EQUIPMENT OF THE ROYAL ARMY MEDICAL CORPS.

With regard to this most important point the Commissioners say,

At the outbreak of the war there were only available staff and equipment for two army corps. An army corps is (approximately) composed of three infantry divisions of 10,000 men each, and 6000 corps troops (cavalry, artillery, engineers, &c.). Even the two army corps which were first employed in the war could only be staffed and equipped with difficulty, as it appears from the evidence of Major Bedford that for the 6th Division the reservists had to be used, and a mixed *personnel* employed. It further appears from the evidence before us that, after providing for the first two army corps, there was existing only a reserve of equipment sufficient to furnish one general hospital and two stationary hospitals. The explanation given for so small a reserve of equipment being kept is, that improvements were being so often made in various articles that it was undesirable to keep a large stock of what might ultimately prove to be out of date and useless. Although this explanation has some force in it, it does not appear wholly satisfactory. With regard to staff, the evidence given by Surgeon-General Jameson, the Director-General of the Army Medical Service, shows that the strength of the Royal Army Medical Corps both in officers and men was completely exhausted in providing the medical attendants for the first two army corps in South Africa, and the general and stationary hospitals which were required in connexion with those two corps. During the year 1900, and especially during the first four months, further troops were rapidly poured into South Africa, and it consequently became necessary for the Director-General at home and the Surgeon-General at the Cape to make provision for the medical service for these troops. The colonial troops, the militia, and the volunteers brought with them only their regimental medical officers, and the whole burden of supplying them with field and base hospitals fell upon the Imperial Government. The only exceptions being, that the Imperial Yeomanry were to a certain extent separately provided with a base hospital, which was stationed at Deelfontein, and subsequently with a branch hospital, which was stationed at Pretoria; and that the New South Wales contingent brought with it the half of an ambulance company which was subsequently, at Surgeon-General Wilson's request, doubled.

The Commissioners then describe how the deficiencies were met.

Having regard to the deficiencies and circumstances above mentioned the difficulties of supplying the army in South Africa with sufficient medical aid became very great, increased as those difficulties were by the enormous range over which the military operations were carried on, and the great length of the lines of communication. As the war progressed and losses occurred in the medical staff, much difficulty was experienced in providing an adequate staff of doctors and orderlies in South Africa. To a great extent this was met by the employment of civil surgeons and untrained orderlies. But the pressure was so great that a special reduction had also to be made in the unit allowances of the field hospitals at the seat of war. The original divisions which came from Great Britain arrived with the proper allowance of these hospitals. But the 9th and 11th divisions were formed in South Africa, and though it was found possible to supply locally these divisions with bearer companies, it was not found possible to supply them with field hospitals. The field hospitals were only supplied by taking away from each of the other divisions its divisional field hospital, and also (though this is not quite so clear on the evidence) the extra field hospital which, as previously stated, is by allowance allotted to each army corps. In other ways the army corps unit allowance of field hospitals was reduced from nine or 10 to six. Major Bedford states that owing to this the field hospitals in South Africa were 10 short of the proper number. This shortage was never made up, and undoubtedly caused a strain throughout the whole of the campaign. While willing to make every allowance for the many difficulties which the medical authorities in South Africa had to contend with in supplying the locally-constituted divisions with field hospitals, it seems strange that when it became evident that it would be necessary to abstract field hospitals from units already organised a demand was not made by the Surgeon-General in South Africa upon the War Office to fill up the blanks that were thus left. There is no evidence to show that this was done. At the same time we have to acknowledge that a field hospital to be efficiently worked must be staffed by a sufficient proportion of trained officers and trained orderlies of the Royal Army Medical Corps. It is only some posts in these hospitals which can be satisfactorily filled by civil surgeons, and at the time we are now dealing with it was very doubtful if a sufficient number of officers was available for the purpose of giving to the *personnel* of the 10 field hospitals required the necessary proportion of Royal Army Medical Corps men. Certainly it does not appear to have been practicable to obtain in sufficient quantities a supply of trained orderlies.

The great need of staff of the Royal Army Medical Corps is exemplified by the fact that when No. 5 General Hospital arrived in South Africa on Jan. 20th, 1900, its *personnel* had to be severed from its equipment and used for the hospitals at the front; its equipment was temporarily stored at Woodstock and was subsequently used for other hospitals. Fortunately, the supply of civil surgeons in the United Kingdom willing to help in the campaign was abundant and, as a rule, of excellent quality, but of necessity some time elapsed before these civil surgeons could be obtained and forwarded to the seat of war. Surgeon-General Wilson in South Africa also enlisted there the services of local practitioners, but the supply of these was very limited. In forming fresh hospitals and utilising these surgeons it was found essential to have a certain number of doctors of the Royal Army Medical Corps in each hospital and an army doctor at the head. The reason for this could not be better stated than in the words of Mr. Bowlby, senior surgeon in charge of the Portland Hospital:—"It is, however, a great mistake to suppose that civilian surgeons, however skilful, can satisfactorily supplant the army surgeons beyond certain limits, and it is certainly my opinion that this limit has been passed a long time ago. Some of the more recently formed general hospitals have had only three or four Royal Army Medical Corps officers for the organisation of the whole 500 beds, or, as at Bloemfontein, 1500 or more; and, as a result, matters have not worked as well as they might. It must be remembered that a young surgeon with civilian training, however brilliant, cannot know anything about such matters as camp sanitation, the duties of ward-masters or stewards, disinfection of clothes and stools, pitching of camps, inspection of food, what orderlies know and can do, and what orderlies do not know and cannot do, and a hundred other things which every physician and surgeon would think of. I am quite certain that the working of these hospitals was made still more difficult by the deficiency in numbers of officers of the Royal Army Medical Corps, and it is my opinion that in all departments of the Royal Army Medical Corps there has been very great personal strain because the work has had to be done with a staff insufficient in numbers."

The difficulty of supplying orderlies accustomed to or fit for hospital work was much greater than the difficulty of finding civil surgeons, and in fact was never overcome. Surgeon-General Wilson in his evidence put the position tersely, though perhaps too strongly, when he said that he was obliged to take all who offered themselves. A good

orderly must be trained, and the training takes some time and clearly ought not to be obtained at the expense of patients in a crowded hospital. Some orderlies were obtained from the St. John's Ambulance Association. These men, though as a body they worked well, were to a great extent untrained and quite unused to hospital work, and some of them appear to have been rough and unfitted for the purpose of tending sick men. Ordinary regimental privates were also largely employed. Some of these privates were soldiers who, though not fit for duty at the front, were able to be about and look after others, and others were convalescents, sufficiently recovered from their illnesses to be able to do nursing duties in the hospitals. There is much difference of opinion in the evidence before us as to whether convalescents should be employed at all for hospital purposes. We see no objection in times of great pressure, when trained orderlies cannot be obtained, in convalescents being employed to assist in hospital work, provided that the convalescents be carefully selected and are found to be in a state of health which renders them able to assist in the work without injury to themselves. But, undoubtedly, they should be used sparingly and only as assistants where there are trained orderlies sufficient and able to properly supervise them. Surgeon-General Wilson, in a circular addressed to the medical officers of the hospitals in South Africa, pointed out the advisability of their employing, when necessary, as assistant orderlies, men who were fit for garrison duty rather than convalescents from fever or other serious disease. But convalescents have been employed in this war at times of pressure. We find cases where it is suggested that men employed as orderlies were not perfectly convalescent or fit to act. It is difficult to say how far this suggestion is well founded. Possibly there may have been cases of the kind, but we have no sufficient reason for thinking that they were at all numerous.

The general work done by the authorities in providing a supply of doctors and orderlies as the war went on appears from the following figures which may be taken to be approximately accurate, though owing to the colonial levies and the temporary employment of local medical men, precise figures are not available.

In the early part of October, 1899, there were in South Africa about 20,000 British troops. By the end of October a further 14,000 men had arrived. During the following six months to April, 1900, reinforcements were poured into the country at the average rate of about 30,000 men a month. During May, June, and July, the reinforcements amounted to about 11,000 men a month. The total number of troops landed between September, 1899, and July, 1900, did not fall short of the aggregate of 230,000 men. At the beginning of September there were in the country about 30 medical officers and 270 hospital subordinates. During September and October, 1899, about 50 medical officers, 1000 hospital subordinates, and 12 nurses arrived, and during the following six months about 600 medical officers (including civil surgeons), 5000 hospital subordinates, and 275 nurses were landed. In all there were landed in South Africa during the period from September to July about 900 medical officers (including civil surgeons), 400 nurses, and 6000 non-commissioned officers and men of the Royal Army Medical Corps and St. John's Ambulance Brigade. At the time of the greatest pressure, which occurred at the end of the month of March, the total force then engaged being about 207,000 men, there were about 800 medical officers (including civil surgeons), 6000 hospital subordinates, and 800 nurses in the country. In July there were remaining available for duty about 224,000 men in the army and the medical staff consisted of about 1000 medical officers (including civil surgeons), 7000 hospital subordinates, and 900 nurses. It must be remembered that although these figures fairly represent the amount of medical aid available in the country generally it does not follow that it was distributed in proportion to the needs of particular localities. The movements of troops were often rapid and unexpected. Transport was generally difficult and had in many cases to be utilised more with a view of supplying the necessities of the fighting line than for the purpose of rendering medical aid, which was therefore often lacking to a more or less extent. These difficulties were very conspicuous at Bloemfontein during the months of April and May, but existed to a less extent at other places and on other occasions.

With regard to the nurses, there was no difficulty found in obtaining a sufficient number of suitable persons, nearly all of whom were properly trained.

With reference to the dispatch of general and stationary hospitals and their equipment of medical and surgical stores, necessaries, and hospital comforts, we consider that from the time the true position of affairs was realised the home authorities did all that was practically possible in procuring and forwarding them to South Africa.

Details as to the hospitals sent out from this country to South Africa and the dates of their arrival there appear in the Appendix (*vide* Appendix—*Bedford* 2), which also contains a statement showing at various dates between the 2nd October, 1899, and the 16th July, 1900, the strength of the Army in South Africa and the corresponding strength at those times of the medical *personnel* (*vide* Appendix—*Jameson* 4).

Speaking generally, we may say that all requisitions from South Africa concerning the care of the sick and wounded there were promptly met by the home authorities, and that no delay occurred here in meeting those requisitions, excepting in forwarding a few things, such for example as ambulance wagons and marquees and some special articles not usually kept in store, and which could not be purchased or obtained quickly.

The efforts of the home authorities were ably supported by the authorities at the base in South Africa, who worked well in procuring local supplies and in forwarding what was required to the front. In these ways there were soon established in South Africa ample supplies of all necessaries and medical comforts, but owing to the difficulties of transport and the large extent of country to which they had to be supplied, it was often found impossible, especially in the case of the advance of the army of Lord Roberts to Bloemfontein and Pretoria, to get necessaries or comforts which existed in sufficient quantities in South Africa, to the exact spot where, or at the exact time when, they were urgently needed. And, accordingly, at certain places and times, there was a want of certain articles required for the sick and wounded. These will be found more particularly dealt with by us in Part III. The only general remark that we need make here is, that throughout the campaign (until quite recently) there was a deficiency of bed-pans and commodes, the lack of which often caused considerable discomfort and even suffering on the part of patients. The great necessity for such articles, especially in a country like South Africa where dysentery and enteric fever are rife, appears not to have been adequately recognised by the medical authorities and was certainly not sufficiently provided for.

Various complaints, often of a sweeping character, have been made on various grounds against the Royal Army Medical Corps in this war. Like every large body of men, the Royal Army Medical Corps has its unfit or bad members, but the evidence justifies us in saying that in this war the proportion of such members to the whole body of the Royal Army Medical Corps is very small. Speaking of the officers as a whole, their conduct and capacity deserve great praise. Their devotion to their duties both at the front and in the fixed hospitals, and the unselfish way in which they have attended to the sick and wounded, often at the risk of life, have been recognised by all impartial witnesses. The number of those who have died during this war in discharge of their duty is unfortunately large.

There were, of course, a few exceptions to the general efficiency, and cases of roughness and inattention to the wants of patients on the part of a few officers will be found referred to when we deal in detail with complaints in Part III. Such few cases naturally led to mischievous results and gave rise to much complaint, and patients who thereby suffered, or persons who saw the suffering, were sometimes apt (perhaps not unnaturally) to judge the Royal Army Medical Corps as a body by those cases, and to make general charges against it.

* * * * * * *

But in connexion with the subject of the general efficiency of officers of the Royal Army Medical Corps we must refer to a fact which ought not to be ignored, either in the interests of the Royal Army Medical Corps itself or of the army generally, and that is the existence on the part of many military officers of a feeling of distrust of the skill and professional experience of doctors of the Royal Army Medical Corps as compared with civil doctors. To a great extent we believe this mistrust to be ill-founded. That it is not wholly unfounded is to be explained by the difficulties under which the officers of the Royal Army Medical Corps have hitherto laboured.

COMPLAINTS CONCERNING OFFICERS OF THE ROYAL ARMY MEDICAL CORPS.

As regards this question the Report states:

The Royal Army Medical Corps has been undermanned even in times of peace, and its staff much overworked. In consequence the majority of the officers have had no sufficient holidays or leave of absence, and no proper opportunities of studying or of keeping abreast with recent advances in the practice of medicine and surgery. The authorities have experienced, probably to some extent in consequence of the above facts, a difficulty in obtaining men of good professional standing to join the Royal Army Medical Corps, and the insufficiency of officers has occasionally led in the present war to men of the Royal Army Medical Corps being employed who were not properly fit for the due discharge of the duties cast upon them. Some few officers who had retired, or practically retired, and who were not fitted for active work, have been employed. Some of these, being senior men, were put in charge of important hospitals; for in the Royal Army Medical Corps the practice of appointing men to the more important posts according to mere seniority appears to be too rigidly adhered to. The result of such appointments has been that the hospitals to which they were appointed as chiefs have not been properly organised or superintended, and the hospitals have suffered in consequence. It should be clearly understood that these exceptional instances were but two or three in number.

We think that steps should be taken immediately after this war is ended, or at some other suitable time, whereby (1) the staff of the Royal Army Medical Corps may be permanently enlarged, and due provision may be made for its further necessary and speedy enlargement in times of great wars; (2) inducements may be offered to ensure a continuous supply to the corps of sufficient men of good professional attainment; and (3) the men who have joined may be kept as a body thoroughly acquainted with the general progress made in professional subjects and at a high professional standard of efficiency.

The means by which the above results can be best attained require careful expert investigation and consideration and cannot be adequately dealt with by us. They should form the principal subject for consideration on the part of the departmental or other committee whose constitution is recommended by us at the end of this report.

As regards the complaints that the officers of the Royal Army Medical Corps are too military in their habits and conduct the Commissioners observe that it must be remembered that all their patients are soldiers, but they go on to say:—

We think that occasionally the military tone of the hospitals has been hard on the ordinary private soldier who is really ill and might well expect when in hospital to be treated very much as a patient would in an ordinary civil hospital. And no doubt the fact that, even while in hospital, he has to regard his doctor as his superior officer has tended to increase his dislike of making complaints even when they might be well founded. We think that this should be remedied, as could easily be done if the views we are expressing were brought to the attention of the officers of the Royal Army Medical Corps and were duly appreciated by them, as no doubt they would be.

As certain attacks have been made against the principal medical officer and head medical staff in South Africa for want of organising powers, and generally for the way in which the campaign in South Africa has been managed from a medical point of view, we must state our views upon this matter.

* * * * * * *

In South Africa the territory occupied by the troops is vast. In this territory numerous armies or bodies of men have been continuously and rapidly changing their positions. Often the army movements have been extremely sudden and no notice of them could be given beforehand to the medical staff. The medical arrangements for all these armies and troops had to be considered and provided for. In addition the medical staff had to consider and provide for the placing and shifting of the various hospitals on the lines of communication and the establishment of the hospitals at the base and the supply and care and transport of all the numerous requisites for sick and wounded men throughout the country occupied by our soldiers.

Of course, judging from events, we know that mistakes have been

made by the staff in the course of this war and that things have not been foreseen which might have been. We have pointed out in dealing with complaints in Part III. instances of such mistakes and oversights. But taking their work as a whole and considering the difficulties they have had to contend with we think that the principal medical officer and his head staff have done excellent work. They have never spared themselves and have shown a great devotion to their duty and every desire to make due provision for the care of the sick and wounded, and when their conduct is fairly judged we think that they deserve great praise. The organisation of the field and stationary and base hospitals for the colonial troops, the militia, and volunteers fell upon the medical staff in South Africa, and in our judgment they met the difficulties presented to them with singular ability and success.

CIVIL SURGEONS: COMPLAINTS AGAINST ORDERLIES.

The Commissioners find that the work of the civil surgeons was, as a whole, well done, and as for the orderlies the way in which these men as a body discharged their duties has deservedly been the subject of high praise from many witnesses of experience. Some of the untrained orderlies who had to be hastily obtained to supply deficiencies were inattentive, rough, and occasionally brutal to patients. But these men were not the trained orderlies of the Royal Army Medical Corps. The report proceeds:—

There are two other matters of importance to be mentioned. We refer to the existence in places amongst the orderlies of the crime of stealing the stimulants and comforts—and even the money and other property—of patients, and also of the practice of taking bribes from the patients for the supply of comforts or for rendering the assistance due to them. There have been too many complaints on these heads brought to our notice for us to consider the cases in which the ill-practices in question have occurred as so exceptional as not to demand serious consideration, though we have no sufficient reason to justify us in concluding that they prevailed to any very large extent. The medical officers do not appear to have been sufficiently aware of their existence. This is to be regretted, for otherwise steps no doubt would have been taken to remedy the evils in question. We think it advisable that the attention of the medical officers of the various hospitals should be specially and speedily called to these matters, with a view to their instituting searching inquiry and stamping out the ill-practices so far as they exist in their hospitals.

PRIVATE HOSPITALS AND CHARITABLE SOCIETIES.

The various private hospitals did excellent work, as well as the Red Cross Society and sundry charitable persons.

But there must have been some waste owing to the overlapping of the various charities and charitable gifts, and to the difficulty of properly distributing the same amongst those who needed them. In future wars it would be advisable, if possible, that some provision should be made by which all charitable gifts should be received and dealt with by one organised body.

RAILWAY TRANSPORT.

Considering that the railways were, as a rule, only single line, of a small gauge, and had only a small rolling-stock, the difficulties of transport were overcome in a most creditable manner.

ADMINISTRATIVE DUTIES OF THE ROYAL ARMY MEDICAL CORPS AND "RED TAPE."

The Commissioners do not think that the administrative duties of the Royal Army Medical Corps could be lightened by the employment of civil administrators, and with regard to "Red Tape" the Commissioners state:—

We believe, shortly speaking, that what is meant from a practical point of view by the use of the term as applied to the Royal Army Medical Corps is: (1) that there are numerous unnecessary returns and records to be filled up and kept by the principal medical officer; and (2) that difficulties and delays ensue from the necessity cast upon the officers of hospitals by the military regulations in respect of the requisitioning of necessaries.

With regard to the first point, no doubt the returns and other documents are numerous. To a certain extent they cannot be avoided. For instance, records of admissions to the hospital, and discharges from it, and also of complaints of the patients, must be kept.

So long as the medical officers are expected and required to answer promptly all inquiries concerning wounded or sick soldiers, the necessity for several full returns and records being kept must be admitted. We do not ourselves feel justified in attempting to point out what returns or records could in time of war be dispensed with; except that in the case of general hospitals we cannot see the necessity for three records being kept, as is ordinarily the case—namely, one by the principal medical officer of the surgical division, one by the principal medical officer of the medical division, and the third by the chief principal medical officer of the hospital. It is possible, however, that the documents might properly be shortened in several respects, and the question as to how this could be effected might also usefully form one of the subjects to be inquired into by the Committee we have already mentioned. We should, perhaps, add that in this campaign civil surgeons were, as a rule, only required to fill up the diet sheets, which, in our opinion, of necessity should be kept by them. As to a complaint that has been made against the classification of diseases in the returns we cannot think that this is well founded. The classification in question is that of the Royal College of Physicians, the Royal College of Surgeons, and is that adopted by the Registrar-General of Mortality in England.

With regard to the second point, it is true that the medical officers have to get supplies for their hospitals, including medical comforts, from the Army Service Corps, and such things as beds, mattresses, &c., from the Ordnance officers. This no doubt does on some occasions cause delay. Whether this can to any and what extent be avoided with practical advantage by permitting the Royal Army Medical Corps to have sole possession of and control over all hospital necessaries (other than ordinary food and ordinary clothing), including such things as beds, mattresses, and hospital clothing, is a question which should be considered by the Committee which we have already mentioned.

Except in respect of special drugs or medical comforts not ordinarily used, and in cases of urgency, the hospital should and in ordinary cases would be properly provided with all requisites, and the medical officers in charge as they fell short of any requisite would requisition for a supply in time, and we believe that apart from special cases those requisitions would be complied with without any unreasonable delay. But in cases of special medicines or instruments, or in cases of urgency, undoubtedly there might be delay, and the difficulty could only be met by giving the medical officers in command of the hospitals full powsr to order and buy on their own responsibility at the expense of the State. Naturally, such a power is one liable to be abused, and ought to be exercised with great care, but there certainly should be such a power given to the officers, and it should be freely used without liability on their part to censure, except in case of abuse.

As a matter of fact, in this war such a power has been exercised to a large extent by many of the medical officers. There is a General Regulation of the Royal Army Medical Corps which points in this direction, but it is limited in scope and not quite explicit enough. Some of the medical officers in South Africa apparently did not know that they had this power, and accordingly did not exercise it.

In Natal Colonel Gallwey expressly issued a circular which dealt with the buying by officers in cases of necessity, and that notice was very efficacious and was promptly acted upon by the medical officers there. In others parts of South Africa an express circular of the kind was not issued, and it would have been better if it had been. Surgeon-General Wilson did send a circular pointing out generally that medical officers in cases of emergency should take the initiative in procuring what was necessary, and stated that he would support them in their acts, but he did not specially refer to the question of buying. It appears from his evidence, however, that he did speak to the principal medical officers on the subject, and told them to exercise the power of buying freely.

TRANSPORT OF THE ROYAL ARMY MEDICAL CORPS.

With regard to the suggestion of the Royal Army Medical Corps having its own transport, the Commissioners consider that there are difficulties in the way of this suggestion being carried out. But they think that general and stationary hospitals should have their own transport which should not be taken away from them.

SANITATION.

In an ordinary hospital the Commissioners consider that the principal medical officer should look after its sanitation.

But when there is a question of the sanitation of a town, or of a large camp, where hospitals exist, we think it is advisable that there should be a special sanitary officer who should be charged with the various larger duties appertaining to sanitation, such as the location of proper camping grounds for the various regiments, fixing sites for hospitals, providing suitable sites for hospitals for sick horses, making arrangements for the removal of refuse and the discharge of the latrines of the hospitals, and so forth. Occasionally in this war special sanitary officers have been appointed in large centres, as, for example in Bloemfontein and in Pretoria, cases which are specially referred to in Part III. But difficulty has been experienced in finding suitable men for such posts. We think that it is preferable that the men to be appointed should be officers of the Royal Army Medical Corps, and that it is advisable, in order that duly qualified special sanitary officers should be forthcoming in future wars when required, that, as part of the organisation and working of the Royal Army Medical Corps, certain members of that body should be specially selected to undertake sanitary duties.

(To be continued.)

THE WAR IN SOUTH AFRICA.

SOUTH AFRICA has been the graveyard of many reputations and the war has given rise to no end of contentious criticism. The public can now read the South African despatches covering the whole period and giving in effect a historical and, in a sense, official outline of the events of the campaign. The study of them is of general interest and does not concern military readers only. They serve to clear up many points which unquestionably needed explanation and to set forth the nature and difficulties of an expedition which has so severely strained and tested, not only the medical, but every branch of the service. The medical service had, of course, in common with the rest of the army, to take its full share of those difficulties which were brought about by the exceptional nature of the campaign and the untoward occurrences which arose in the course of it. How far, however, these could and should have been foreseen or guarded against and provided for by timely and adequate hospital arrangements is a question which is bound to be threshed out in Parliament during the present session.

Cases of plague still continue to make their appearance at Cape Town, but the disease has not happily shown any signs of rapid extension. The cases have been few

so far and the disease is stated to be of a much less severe type than that which prevailed in Bombay, but the local authorities fear that some cases are being concealed. Be this as it may, the outbreak is very embarrassing in that it seriously interferes with the employment of native labourers and with the work at the Cape Town docks, in addition to causing a certain amount of anxiety inseparable from the mere fact of its presence.

The war news from South Africa is, on the whole, satisfactory. There is great activity on the part of the British in pursuit of the Boer forces. The sweeping method adopted by Lord Kitchener's policy is being systematically pursued. The object is apparently, as we have said, to drive the Boers into certain positions and localities where, deprived of cattle, horses, forage, ammunition, and supplies generally, they will have to fight in order to live, instead of, as has been hitherto the case, living in order to fight. It appears at the moment of writing that both Botha's and De Wet's forces are in tighter situations than they have hitherto been. Those of the British and colonial troops who have been for a long time in the field are all more or less fatigued and getting what is termed stale. We may feel confident of their determination, however, to spare no effort to bring the war to an end. All this desultory fighting in various directions on a small scale adds to the number of wounded who are admitted to the surgical side of hospitals, but it is on the medical side and chiefly from enteric fever and other forms of disease that the sick lists are maintained.

"RETURN" CASES OF SCARLET FEVER AND DIPHTHERIA.

IN February, 1900, the Metropolitan Asylums Board asked the Royal College of Physicians of London for an expression of opinion as to certain cases of scarlet fever and diphtheria which had been discharged from the Board's hospitals as recovered but had nevertheless been alleged to prove sources of infection on returning home.[1] The reply of the College was considered by the Board at its meeting held on Feb. 2nd; it contained the three following recommendations, which the medical superintendents of the Board's hospitals have been authorised to carry into effect:—

1. That in each hospital a couple of wards identical in respect to cubic space per bed, &c., should be set aside and administered on a different principle, the sex of the children being the same, and the age as far as possible; that in one ward the cases subject to mucous discharges from nose or ear be rigorously excluded; that immediately on the appearance of any such discharge the patient should be removed, and that all nozzles of syringes should be kept in antiseptic solutions. In the other ward no special attention should be paid to these discharges other than that hitherto adopted. The incidence of either rhinorrhœa or otorrhœa should be compared. Cases of "septic scarlet fever" should be excluded from both.

2. That, if possible, in certain hospitals, with the approval of the medical superintendent, two or more rooms previously disinfected be reserved for the isolation after six or eight weeks' detention of single patients who are suffering from rhinorrhœa or otorrhœa, but whose desquamation is completed. Each patient so secluded should be kept for 10 days or a fortnight before returning home. During this period of detention the affected parts should be regularly irrigated or syringed with some reliable antiseptic, and great care should be taken that the nozzle of the apparatus be kept in a germicidal solution. On the expiration of the quarantine the patient should be sent home whether the discharge has ceased or not, and the room should be disinfected prior to the reception of another patient. The subsequent history of the case should be investigated.

3. That the inquiry into the facts connected with the incidence of the return cases at the managers' hospitals should be continued for a period of 12 months, and that the scope of the inquiry should include the history of the cases discharged under the conditions mentioned.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6853 births and 4408 deaths were registered during the week ending Feb. 16th. The annual rate of mortality in these towns, which had been 16·4 and 19·8 per 1000 in the two preceding weeks, declined again last week to 19·5. In London the death-rate was 19·3 per 1000, while it averaged 19·6 in the 32 provincial towns. The lowest death-rates in these towns were 11·7 in Burnley, 13·3 in Bradford and in Huddersfield, 13·9 in Cardiff, and 14·3 in Preston; the highest rates were 22·7 in Birkenhead, 22·8 in Birmingham, 25·1 in Plymouth, 27·3 in Norwich, and 28·8 in Liverpool. The 4408 deaths in these towns included 348 which were referred to the principal zymotic diseases, against 323 and 397 in the two preceding weeks; of these 105 resulted from whooping-cough, 78 from measles, 71 from diphtheria, 35 from diarrhœal diseases, 32 from "fever" (principally enteric), and 27 from scarlet fever. No death from any of these diseases occurred in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Norwich, Bradford, and Newcastle, and the highest rates in Bristol, Birkenhead, Liverpool, Manchester, and Salford. The greatest proportional mortality from measles occurred in Liverpool and Bolton; and from whooping-cough in Plymouth, Bristol, Birkenhead, and Salford. The mortality from scarlet fever and that from "fever" showed no marked excess in any of the large towns. The 71 deaths from diphtheria included 20 in London, six in Salford, five in Manchester, five in Leicester, and four in Leeds. No fatal case of small-pox was registered last week in any of the 33 towns, and only one small-pox patient remained under treatment on Saturday last, Feb. 16th, in the Metropolitan Asylums hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1876, against numbers declining from 2535 to 1963 on the seven preceding Saturdays; 142 new cases were admitted during the week, against 172, 178, and 145 in the three preceding weeks. Influenza was certified as the primary cause of 16 deaths in London last week. The deaths referred to diseases of the respiratory organs in London, which had been 323 and 397 in the two preceding weeks, further rose last week to 420, but were 68 below the corrected average. The causes of 62, or 1·4 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Salford, Bradford, Leeds, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Sheffield, Gateshead, and Newcastle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·1, 22·2, and 23·2 per 1000 in the three preceding weeks, declined again to 22·6 during the week ending Feb. 16th, but showed an excess of 3·1 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 18·0 in Aberdeen and 19·7 in Dundee to 25·2 in Glasgow and 26·9 in Perth. The 710 deaths in these towns included 33 from whooping-cough, 25 from measles, 20 from small-pox, 10 from diphtheria, 8 from diarrhœa, six from scarlet fever, and four from "fever." In all, 106 deaths resulted from these principal zymotic diseases, against 126 and 103 in the two preceding weeks. These 106 deaths were equal to an annual rate of 3·4 per 1000, which was 1·9 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 43 and 37 in the two preceding weeks, further declined last week to 33, of which 25 occurred in Glasgow, six in Dundee, and two in Paisley. The deaths from measles, which had declined from 23 to 14 in the four preceding weeks, rose again to 25 last week, and included 15 in Edinburgh and seven in Aberdeen. The fatal cases of small-pox, which had been 11, 24, and 11 in the three preceding weeks, rose again last week to 20, and were all registered in Glasgow. The deaths from diphtheria, which had been seven in each of the two preceding weeks, increased to 10 last week, and included six in Glasgow. The fatal cases of diarrhœa, which had been 27 and 18 in the two preceding weeks, further declined last week to eight, of which six occurred in Glasgow. The six deaths from scarlet fever corresponded with the number in the preceding week, and included four in Glasgow, where three of the four deaths from "fever," were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 123 and 148 in the two preceding weeks, declined again last week to 153, and were 172 below the number in the corresponding period of last year. The causes of 29, or more than 4 per

[1] THE LANCET, April 21st, 1900, p. 1162.

cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·4 and 34.0 per 1000 in the two preceding weeks, further rose to 34·3 during the week ending Feb. 16th. During the past four weeks the death-rate in the city has averaged 31·0 per 1000, the rates during the same period being 17·9 in London and 20·5 in Edinourgh. The 228 deaths belonging to Dublin registered during the week under notice were two in excess of the number in the preceding week and included 10 which were referred to the principal zymotic diseases, against 20, 18, and 16 in the three preceding weeks; of these, three resulted from whooping-cough, two from scarlet fever, two from "fever," two from diarrhœa, and one from measles. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·7 in Edinburgh. The fatal cases of whooping-cough, which had been 12 and 9 in the two preceding weeks, further declined last week to three. The deaths from "fever," which had been three and five in the two preceding weeks, declined again to two last week. The 228 deaths in Dublin last week included 31 of children under one year of age and 71 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons exceeded the number in the preceding week. Six inquest cases and three deaths from violence were registered; and 83, or more than a third, of the deaths occurred in public institutions. The causes of six, or nearly 3 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon H. Todd to the *President* for course of hospital study. Staff Surgeon H. W. Macnamara to the *Ophir*. Surgeons: P. N. Randall to the *Duke of Wellington;* W. R. Knightley to the *Harrier;* R. Hill to the *Ophir;* W. H. Daw to the *Rambler;* and A. H. Prichard to the *Antelope*.

The following qualified candidates for the Royal Navy Medical Service have been appointed to be surgeons in His Majesty's Fleet:—Edmund Cox, John Macdonald, Arthur La Touche Darley, William Edward Ruttledge, Thomas Francis O'Keeffe, Charles Edward Cortis Stanford, Ernest Fitzgerald Ellis, August Joseph Wernet, George Charles Cumberland Ross, Percy Francis Alderson, Douglas Victor Lowndes, John Thornhill, Henry Constantine Woodyatt, and Arthur Richard Thomas.

ROYAL ARMY MEDICAL CORPS.

Lieutenant C. H. Furnivall is to do duty at the Station Hospital, Poona. Lieutenant A. M. Sparkes is detailed to assist the Embarking Medical Officer at Southampton. Major R. P. Bond is posted to the Western Heights, Dover, for duty.

The undermentioned officers retire on retired pay:—Lieutenant-Colonel J. G. W. Crofts and Major J. Harran. Captain T. H. M. Clarke, D.S.O., is seconded whilst his services are placed at the disposal of the High Commissioner of Crete. The undermentioned Lieutenants to be Captains:—H. O. B. Browne-Mason, F. S. Penny, B. Watts, H. G. Martin, J. G. Berne, F. F. Carroll, J. D. G. Macpherson, W. P. Gwynn, S. de C. O'Grady, A. H. O. Young, E. A. Bourke, M. M. Lowsley, A. C. Lupton, G. B. Carter, N. H. Ross, P. H. Collingwood, and C. J. O'Gorman. Civil Surgeon R. McKenzie Skinner, serving in South Africa, to be Lieutenant.

The following candidates were successful at the Royal Army Medical Corps examination recently held in London for commissions:—F. W. Lambelle (2750 marks), L. J. S. Cahill (2649 marks), W. C. Stevenson (2258 marks), M. C. Beatty (2220 marks), R. L. Hagger (2171 marks), H. W. Long (2098 marks), and J. R. Welland (1905 marks).

INDIA AND THE INDIAN MEDICAL SERVICES.

Lieutenant-Colonel Charles Little, Madras Establishment, is promoted to Colonel.

At the Indian Medical Service examination held in London on Feb. 8th the following candidates were successful:—

Name.	Marks.	Name.	Marks.

MILITIA MEDICAL STAFF CORPS.

The undermentioned Surgeon-Lieutenants to be Surgeon-Captains: A. H. Benson and W. Fletcher. The transfer of Surgeon-Lieutenant W. E. M. Corbett from the 2nd Volunteer Battalion the Devonshire Regiment is cancelled at his own request.

VOLUNTEER CORPS.

Rifle: 1st Cadet Battalion the Queen's (Royal West Surrey Regiment): Acting Surgeon Arthur Charles Elliman to be Surgeon-Lieutenant. 1st Cadet Battalion the Buffs (East Kent Regiment): Acting Surgeon Charles Walter Scott to be Surgeon-Lieutenant. 4th Volunteer Battalion the Bedfordshire Regiment: The undermentioned gentlemen to be Surgeon-Lieutenants: Edward John Cross and William Fellowes Fisher. 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Major R. S. Gibb resigns his commission and is granted the rank of Surgeon-Lieutenant-Colonel, with permission to wear the uniform of the battalion on his retirement. 2nd Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant D. L. Davies to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Aberdeen Company: The undermentioned gentlemen to be Surgeon-Lieutenants (Supernumerary): William Archer Irvine Fortescue, Francis Kelly, Alexander Ogston, and Thomas Fraser.

SOUTH AFRICAN NOTES.

Lieutenant J. Matthews, R.A.M.C., reported missing, is believed to be a prisoner (Belfast, Feb. 13th).

Lieutenant J. J. W. Prescott, R.A.M.C., is reported to have broken his collar-bone through a fall from his horse, near Knelfontein (Feb. 3rd).

Progress Report.—Civil Surgeon Bruce, improving (Newcastle, Feb. 14th). Civil Surgeon Williams, progressing favourably and convalescent (Feb. 15th). Lieutenant Forbes-Winslow, R.A.M.C., rather better, and Civil Surgeon Mowatt, no change, Pretoria (Feb. 16th). Civil Surgeon J. J. O'Reilly, dangerously ill (Kimberley, Feb. 16th).

The following officers were discharged from hospital to duty for the week ending Feb. 10th:—Major R. Holyoake, R.A.M.C., Civil Surgeons A. C. Hunter, G. R. Thompson, and Lieutenant W. H. S. Nickerson, R.A.M.C.

Inspector-General of Hospitals and Fleets Henry Charles Woods, M.D., M.V.O., has been promoted to a Commandership of his order.

Surgeon-Captain A. Mackenzie of the 4th Battalion the Somerset Light Infantry (Militia), Taunton, has been recommended for the Royal Humane Society's medal for endeavouring to save a Swede from drowning at East London, South Africa.

ROYAL COLLEGE OF SURGEONS IN IRELAND: DENTAL EXAMINATION.—The following candidates having passed the necessary examination have been admitted Licentiates in Dental Surgery of the College: Mr. Henry Earith Hayes and Mr. Daniel Leveck Rogers.

VACCINATION AT EXETER.—At the meeting of the Exeter Corporation of the Poor held on Feb. 12th it was reported that during the half year ended Dec. 31st, 1900, there were 476 births registered, 342 cases of successful vaccination were certified, 17 certificates of conscientious objection were granted, 51 children died unvaccinated, and the vaccination of 48 was medically postponed. The average of conscientious objections was below that for the corresponding half of 1899.

Correspondence.

"Audi alteram partem."

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr. William Carter, having collected facts which prove that a high mortality is caused by excessive indulgence in alcohol, demands that something shall be done. THE LANCET endorses his views, "A Country Practitioner" endorses THE LANCET, and I am happy to endorse "A Country Practitioner." But the difficulty is to know what to do. We are hardly pioneers. The discovery that alcohol is the cause of many ills has been made some thousands of times during (historically) at least 5000 years, and some hundreds, if not thousands, of attempts have been made to deal with the evil—to do something. Some of these attempts have been more or less successful. Occasionally despotic power has succeeded. But despots do not live for ever, and despotic power is apt to change its objects. Occasionally religious fanaticism has succeeded, but only when it has limited intercourse with more free if more drunken communities to such an extent that its adherents are made barbarous as well as sober. The Turks are a case in point, and their temperance propaganda has been assisted by such persuasive means as the pouring of molten lead down the throats of drunkards. We who live under civilised conditions have a harder task. It is admitted on all hands that the difficulty of the temperance problem increases proportionately with the density of the population. It is greatest in towns. Now the least populated English county (Westmoreland) has 84 inhabitants to the square mile, and England is studded with great cities. Many attempts at temperance reform have been made in civilised countries—the United States, Canada, Scandinavia, Australia, and New Zealand, for example. Will Dr. Carter or anyone else tell us of a single instance in which they have been successful in a town of even so few inhabitants as 10,000, or in rural districts when the density of the population was half that of Westmoreland. Nay, can they tell us of an instance when public law-breaking resulting in public degradation (including increased drunkenness) has not followed on such an attempt. No doubt we could by Act of Parliament instantly make England more sober than at present. But only for a time. The open sale of drink would be disorganised, and men perforce would be temperate till the secret sale were organised. Then, following the rule elsewhere, they would be more drunken than ever, and the secret drinking and lawbreaking would have their other attendant evils.

I am, Sirs, yours faithfully,

Southsea, Feb. 16th, 1901. G. ARCHDALL REID.

To the Editors of THE LANCET.

SIRS,—The medical profession and the public generally owe to you a debt of gratitude for your very able and interesting leading article on "Legislation against National Intemperance." If such views reflected the judgment of the medical profession as a whole a volume of example would be set up that would do more to diminish intemperance than 50 years of legislation. Cannot some effort be made to establish a common doctrine in the profession? The modern view, in my opinion, is: (1) alcohol is *not* a stimulant; (2) alcoholism is a defect of will in relation to intoxicants (e.g., alcohol in England, &c.; ether in Ireland, where vast quantities are taken; opium amongst Mohamedans, who are forbidden alcohol); and (3) the predisposing cause of alcoholism is nervous instability of every kind. The children of parents with physical weakness take to narcotics like ducks to water. If the public were aware of this, playing with fire would not be so lightly risked. Alcoholism can no more be cured by imprisonment than can morphinism.—I am, Sirs, yours faithfully,

ASPINALL MARSDEN, M.R.C.S. Eng., &c.

Lightcliffe, Yorks, Feb. 18th, 1901.

To the Editors of THE LANCET.

SIRS,—May I express a hope that your powerful leading article and the correspondence it will call forth may result in some organised effort on the part of the medical profession to educate public opinion in this matter of serious national importance? I quite agree with the remarks of a "Country Practitioner" with the exception that I find it quite possible to be candid on the question of the abuse of alcohol and at the same time retain publican patients, many of whom are perfectly conscious of the evils of their trade and are temperance reformers at heart. Now that the great body of our profession, consultants and general practitioners, are alive to the evils resulting from the habitual abuse of alcohol, while we constantly have evidence of the hopelessness of expecting the two great political parties in the state to treat the subject on non-party lines as one of national urgency, I would suggest that we do, as we have done in other matters of grave importance to the public health, force the questions upon the public and so in time upon the state. Several of our most influential consultants are known to be in favour of temperance reform and a strong council for the "promotion of legislation against national intemperance" could easily be formed.

Only the other day the manager of one of the largest public-houses in my district told me that women were his best customers and that they were not the wives of the lowest class of men but of skilled mechanics earning from £2 to £3 a week. All of us in general practice in London must constantly see small babies in perambulators blocking up the doorways of the public-houses as late as 11 and 12 o'clock at night and their brothers and sisters playing hide and seek round the different bars whilst their mothers are inside drinking. The sending of children to public-houses for drink is an evil, but the evil of allowing mothers to take their children with them and keep them in the physical and moral atmosphere of a public-house up to 12 o'clock at night is one attended with more far-reaching consequences. Educated public opinion has compelled the State to interfere in many ways between parent and child in the interest of the latter, so surely it could do something to put a stop to this most pernicious form of cruelty.

I am, Sirs, yours faithfully,

London, W., Feb. 17th, 1901. M.D., B.S. Lond.

"THE SURGERY OF PREGNANCY AND LABOUR COMPLICATED WITH TUMOURS."

To the Editors of THE LANCET.

SIRS,—All obstetricians must have read with great interest Mr. Bland-Sutton's excellent lecture on ovarian tumours complicating pregnancy and labour. It seems to me that all of them will not accept the very decisive conclusions at which he arrives. That the proper practice when an ovarian tumour is detected during pregnancy is to remove it by ovariotomy is consistent with modern opinion, and no one, nowadays, I think, would recommend any other treatment. That cœliotomy is the only admissible procedure when an ovarian tumour is impacted in front of the fœtal head in actual labour and that puncture of the tumour is always bad practice is, I venture to think, a sweeping conclusion which facts do not justify. If in every such case the services of a skilled gynæcological surgeon, expert in all the details of modern abdominal surgery could be obtained I do not doubt that cœliotomy would be the most hopeful procedure. But consider how exceptionally such expert attendance, with all the necessary appliances, can be had. I can imagine few conditions more trying for the practitioner, or more hopeless for the patient, than such an abdominal section performed on the spur of the moment by a man who has not previously had the opportunityof practising this sort of work.

Nor do I see that Mr. Bland-Sutton has at all proved that puncturing the tumour impacted in front of the presenting part is either an unscientific or a hopeless procedure. The tumour in such a case is necessarily very small. If it had been large it would have risen into the abdominal cavity with the enlarging uterus. A simple aspiration, therefore, with proper antiseptic precautions would, under such circumstances, I submit, be a comparatively safe procedure, which might avert such a formidable operation as was found to be necessary in one of Mr. Sutton's cases in which the impaction of the fœtal head in the pelvic brim necessitated a Cæsarean section as well as an ovariotomy. In McKerron's paper 43 cases are tabulated in which this practice was adopted, in which eight of the

mothers died, a mortality large beyond doubt, but much less than that following either re-position or allowing the head to squeeze past the undiminished tumour. It is to be noted, moreover, that in most of these cases re-position had previously been attempted, so that the tumour had necessarily been subjected to mechanical injury, and also that most of them occurred many years ago before the days of strict antisepsis. It is difficult to see why a simple aseptic puncture should be branded as "an unsurgical procedure," since it may not only obviate the necessity of a Cæsarean section, but of the almost more formidable danger of an ovariotomy by unskilled hands during the actual progress of labour. If the contents of the tumour were found to be of such a character as to prevent its collapsing, then, of course, ovariotomy must at once be proceeded with.

In some of these cases, since the tumours are necessarily small and generally with long pedicles (Mr. Bland-Sutton says: "As is always the case in such circumstances it had a long and slender pedicle") vaginal ovariotomy might possibly be successfully practised. McKerron gives three cases in which this alternative was adopted, in all of which the mothers recovered.

While I do not question that in such hands as Mr. Bland-Sutton's cœliotomy is the practice which should be adopted, he has not convinced me that I was wrong in writing of these cases in the last edition of my book on midwifery: "It is to be noted, however, that accurate diagnosis as to the character of the tumour is not generally possible and it seems to me that, with careful antisepsis, a preliminary puncture is the simplest and probably the safest procedure."

I am, Sirs, yours faithfully,

Grosvenor-street, W., Feb. 15th, 1901. W. S. PLAYFAIR.

To the Editors of THE LANCET.

SIRS,—If you will print the inclosed remarks made by Dr. Herman before the Obstetrical Society in 1898 your readers will be able to read for themselves his advocacy of vaginal tapping. I am, Sirs, yours faithfully,

Cavendish-square, W., Feb. 18th, 1901. J. BLAND-SUTTON.

[INCLOSURE.]

Adjourned Discussion on Dr. McKerron's Paper on "The Obstruction of Labour by Ovarian Tumours in the Pelvis."

Dr. Herman said that Dr. McKerron's paper was the fullest account of the complication of labour with ovarian tumours that had yet been given. He (Dr. Herman) agreed in the main with Dr. McKerron's advice, but there was one method of treatment, the credit of which he believed Dr. McKerron had given to Fritsch, which he thought deserved fuller consideration and commendation than Dr. McKerron had given to it—viz., the making an incision into the cyst through the vagina and stitching the opening in the cyst to the margins of the vaginal incision. In this way the emptying of the cyst contents outside the peritoneum was secured. If the cyst were a dermoid, as many of the cysts which obstructed labour were, simple tapping was attended with much danger of the cyst contents escaping into the peritoneal cavity and setting up peritonitis. (Of the 43 cases in Dr. McKerron's paper treated by tapping or incision 24 died.) This danger was avoided by Fritsch's procedure. He (Dr. Herman) did not advise this for tumours that could be pushed up, nor for those which came under the care of experienced operators in circumstances suitable for the performance of ovariotomy. But many of the cases occurred in the practice of accoucheurs having little or no experience in ovariotomy. The time at which the reposition of an ovarian tumour became impossible was in the second stage of labour, when the tumour was driven down by the advancing presenting part of the child. At this time prompt treatment was needed; there was not time to place the patient under the care of an experienced surgeon. In such circumstances he thought incision and suture was the best course which an accoucheur inexperienced in operating could follow. If such a case came under the care of an experienced operator he inclined to agree with Professor Spencer in thinking the abdominal mode of operating better than the vaginal. If the tumour was driven down into the pelvis there was usually tension of its pedicle; and tension of the pedicle called for extreme care in tying it, produced risk of the knots slipping and the compression of the vessels being imperfect, with hæmorrhage as the result, and such after-hæmorrhage it would be almost impossible to stop by vaginal treatment.

"MR. VICTOR HORSLEY'S REPORT."

To the Editors of THE LANCET.

SIRS,—I have read Dr. Bruce's letter in your last issue with feelings of astonishment and regret. Without communicating with me previously he tells you and through you my constituents that my last report to them was incorrect and "my dicta in the highest degree misleading." After this grave general charge against my accuracy he goes on to state that "it is as nearly as possible the opposite of the truth to say that the representatives of the friendly societies would never consent to the question of the wage-limit being discussed at the Conciliation Board. On the contrary this was one of the questions which we (*sic*) expressly deferred for discussion until such a board would be formed." Dr. Bruce thus raises a plain issue. Although he does not make the direct statement the reader of his letter can only assume that the committee of the General Medical Council, of which Dr. Bruce is a member, had at one time or another agreed with the representatives of the friendly societies that they should defer the discussion of the wage-limit question to the meeting of the Conciliation Board. As I knew that no arrangement of this kind existed in the official documents on this subject open to me I telegraphed to Dr. Bruce and asked him to give me reference to the record of this transaction which he advanced in your last issue and on which he founded his charge against the accuracy of my report. I was not in the least degree surprised to receive the following telegram from him: "No record published agreed to first sitting." We are, therefore, to take it that some secret meeting took place and that we are indebted to Dr. Bruce's memory alone for what passed at that meeting. I must now prove, first, that Dr. Bruce's memory has played him false; second, that it is not my facts which are incorrect, but his; and third, that it is not my statements which are misleading, but his own. As reported in the minutes of the General Medical Council, 1899, p. 530, the Committee of the General Medical Council on Medical Aid Associations, of which Dr. Bruce is a member, held a formal conference with the representatives of the friendly societies on May 4th, 1898. A verbatim shorthand report of this conference was issued to the members of the Council on June 5th, 1899. At this conference the question of the wage-limit was brought up. The hostility of the representatives of the friendly societies to it was both unanimous and extreme, with the result that the question was finally and absolutely put into the background. From beginning to end of the conference in question there was not a single word said about this matter being deferred for discussion at the Conciliation Board. On the contrary it was expressly declared from the chair before the formation of a board was raised that the question of wage-limit was disposed of. Whatever Dr. Bruce may remember as having occurred at some previous secret conference of which according to his own statement no record is open to myself or others of his colleagues, that is of necessity entirely obliterated by what passed at the subsequent conference on May 4th, 1898. As we are in possession of a verbatim printed report of the proceedings of that meeting there is no room for any misunderstanding or lapses of memory as to what was the attitude of the representatives of the friendly societies on the question of wage-limit. Dr. Bruce makes a kindly reference to my anxiety for the interests of my constituents, the registered practitioners of England and Wales. I should be betraying those interests if I failed to report accurately and faithfully as known to me the facts bearing upon questions towards which I am placed in a judicial and fiduciary position. I have had to bear what I suppose is an average number of misrepresentations of my public acts since my election to the General Medical Council, but this charge of inaccuracy now formulated by Dr. Bruce, the Direct Representative of Scotland, is not only the most painful but the most untrue of them all.

I am, Sirs, yours faithfully,

VICTOR HORSLEY.

P.S.—Since writing the above Dr. Bruce has sent me the following by letter in response to several telegrams from me asking him whether May 4th, 1898, or what was the precise date on which his imaginary arrangement with the friendly societies' representatives was arrived at. "It is terrible to be pelted with telegrams with no records to refer to. 'May 4th, 1898,' has receded into the utterly hazy distance with me. Why not try Glover? He must have some sort of journal. I never kept anything of the kind." To comment on Dr. Bruce and his methods of conducting the public business of the profession would be waste of your readers' time.

THE OUTBREAK OF DIPHTHERIA AT OLD HEATH.

To the Editors of THE LANCET.

SIRS,—Your article in THE LANCET of Feb. 9th, p. 426, upon the outbreak of diphtheria at Old Heath, Colchester, describing the attitude taken up by Dr. George Brown, the

medical officer of health of Colchester, opens up more than one question of some importance. Even those of us whose experience agrees with that of Mr. E. A. Hunt in the treatment of diphtheria by means of the injection of antitoxin cannot admit that any practitioner should be coerced into using it. At the same time, as Dr. Brown has stated that he possesses a remedy for the disease which is of greater value than antitoxin and that the results of his method of treatment "are incomparably superior and more satisfactory than those given by the serum treatment," he must surely be in a position to prove his statement and only good could arise by permitting others to know of the details of his method. Indeed, in view of the fact that the patients of other practitioners are admitted to the fever hospital, the latter are certainly entitled to have demonstrated to them that the treatment in the institution will be satisfactory to them; otherwise it is hardly to be expected that they will advise the removal of those under their care, and the community for the well-being of which the medical officer of health is responsible will necessarily suffer.

I am, Sirs, yours faithfully,

HERBERT JONES,
Medical Officer of Health, Herefordshire Combined Districts.

Hereford, Feb. 16th, 1901.

"ARSENICAL BEER POISONING."

To the Editors of THE LANCET.

SIRS,—Permit me to point out that in your report of my contribution to the discussion on this subject at the meeting of the Royal Medical and Chirurgical Society on Feb. 12th my opening remarks are not quite correctly reported in that they perhaps seem to cast an element of reproach on my Manchester *confrères* for not detecting the cause of the epidemic earlier, whereas nothing could have been further from my intention than to imply any such reflection. Those who were present at the meeting will bear me out that after speaking in terms of high praise of Dr. Reynolds's discovery of the cause of the epidemic I somewhat playfully remarked that in a certain work on forensic medicine, the author of which I stated should be nameless, there occurred the statement that "in cases of peripheral neuritis of doubtful origin it is advisable to carefully examine the urine for arsenic." I, in common I am sure with many others, have nothing but admiration for the skill with which the mystery of the epidemic has been elucidated by Dr. Reynolds, Dr. Dixon Mann, Professor Delépine, and others.

I am, Sirs, yours faithfully,

Weymouth-street, W., Feb. 19th, 1901. ARTHUR P. LUFF.

THE COVENTRY DISPENSARY.

To the Editors of THE LANCET.

SIRS,—I am sure that your readers will agree that the profession of medicine is much indebted to the Birmingham and Midland Counties Branch of the British Medical Association for their attitude in refusing to give professional recognition to the medical officers of the Coventry Dispensary until they either bring their institution into line with professional opinion or resign the appointments they hold. Out of some 110 members present at the meeting there were but six dissentients, and it is gratifying to find that in such a meeting so many men were banded together in the common interests of reform.

If other cities were to take a decided stand against such institutions there would be less heard of professional abuse, and medical attendance upon any and all-comers irrespective of their means and position for so paltry a sum as that often offered would cease to exist. At the same time the fact would be brought home to medical men that in visiting members of dispensaries and benefit clubs financially they (the medical men) would be the losers, for it is absolutely impossible that a few shillings a year would repay the medical man for serving a lay committee. He must sooner or later recognise that he is "farmed" by such committee of laymen or that he is willing to give his services for philanthropic motives.

My suggestion is that immediate steps should be taken in other localities, through the British Medical Association and the press, to condemn any medical practitioners holding appointments in institutions not conducted upon lines in accordance with professional opinion, supposing, of course, due and sufficient warning had been given to them. After such condemnation, a reasonable time being allowed for alteration of their conduct, any practitioners transgressing should be indicted before the General Medical Council as being the servants of laymen who exploited them for pecuniary gain, and, if I mistake not, their positions would be analogous to that of Dr. Irvine and the Birmingham Consultative Institute.—I am, Sirs, yours faithfully,

Coventry, Feb. 19th, 1901. EDWARD PHILLIPS.

SCARLET FEVER AND HOSPITAL ISOLATION.

To the Editors of THE LANCET.

SIRS,—Will you allow me to correct the report in THE LANCET of Feb. 16th, p. 477, of my remarks at the meeting of the Society of Medical Officers of Health on Feb. 8th? I said a good deal more than is reported, but with this I shall not deal. I did not say that isolation hospitals were everywhere overcrowded—this we know is not the case. What I did say was that they were very commonly too small for the requirements of the districts to which they belonged, and frequently overcrowded, which is a very different thing. Again, I did not say that our own hospital was grossly overcrowded, but that it had at times been greatly overcrowded in the attempt with inelastic accommodation to meet the requirements of epidemic conditions. It is certainly not overcrowded at the present time.

I am, Sirs, yours faithfully,

Nottingham, Feb. 16th, 1901. PHILIP BOOBBYER.

"MEDICAL CERTIFICATES AND THE LONDON SCHOOL BOARD."

To the Editors of THE LANCET.

SIRS,—It is surely obvious that the certificate system of the School Board wants alteration and I would suggest that some such arrangement as the following should be agreed upon. In the case of a child or of a teacher, if the patient or the patient's legal guardians can pay for a certificate let them do so. If they are too poor, and the medical man in attendance likes to give one out of charity let him do so, but if not, when a patient under the board cannot get a certificate the fact might be reported to the board. The medical officer might then write to the practitioner in attendance and inform him that it is his duty to see the patient and he should ask the practitioner to fix a time when they could meet over the case. If the practitioner chose to attend he should get a fee of, say, 1*s.*, after the scale for notification of infectious disease as regards a patient connected with a public institution. If he did not choose to attend he would get no fee and the medical officer of the board would be in a perfectly correct position. The medical officer draws a large salary and it seems to me that it is his plain duty to sign medical certificates for the board when required. The shilling should be paid by the board, for I do not fancy that many cases would arise where the above arrangement would have to be carried out.

I am, Sirs, yours faithfully,

INTERESTED.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Reforms and Improvements in the Indian Medical Service.—Further Increase of the Plague Epidemic.—Miscellaneous News.

IN order to relieve officers of the Indian Medical Service proceeding on furlough the Government of India have sanctioned the engagement of 20 private medical practitioners. In addition to this temporary measure I understand that it has been practically settled to increase the permanent strength of the service, and in addition also to create an asylum service, which will be open to officers who have had special experience of the insane. The pay for this branch also will be sufficiently attractive to draw in men from outside. I understand also that the jail service will be improved so that those officers who wish to devote their energies in this direction for a long period will be duly

rewarded. The long-looked-for re-opening of leave is daily expected, as in addition to the assistance sanctioned from outside 20 officers have returned from China. It is said that the constant work of the past few years has caused officers to break down at their posts and that the amount of invaliding is becoming serious. The private medical practitioners will be engaged for one year. The pay offered is Rs.600 a month for those holding a diploma in public health and Rs.500 a month for others not so qualified.

The plague deaths throughout India have again increased in number this week—viz., from 3277 to 3396. The increase is entirely in Western Bengal and Bombay city. The figures for Bengal are 2261 against 2181 last week. Patna returns 1231 deaths; Saran, 543; Monghyr, 284; Gya, 181; and Calcutta, 54. In Mysore there is a decline from 367 to 272, and in the Punjab from 55 to 23. In Bombay city, however, there has been a great rise. Last week 308 deaths were recorded, whereas the deaths to-day are put at 427. There are six European cases in hospital, all mild. Of the total deaths from plague last week there were only seven children. Since these figures were published the mortality has risen still further, the deaths for Jan. 30th alone having exceeded 100. The general mortality of the city is very high, 1419 deaths having been reported during the past week—a rate of 89 per 1000 per annum. During the past week plague has threatened to break out in two other quarters—viz., at Karachi and at Benares. In the district of the latter city several cases apparently occurred before the disease was recognised. Two villages are infected. Karachi city is once more threatened. An indigenous case is reported and large numbers of dead rats have been found in the market quarter.

The hospital ship *Carthage* has just arrived from Taku after a splendid voyage, bringing three medical officers in charge of 82 native invalided soldiers and about 100 followers. The alterations in the hospital ship *Gwalior* having been completed she will leave Calcutta for Hong-Kong on March 6th.

A severe outbreak of beri-beri has continued in the 2nd Madras Infantry for some time, causing sickness in about 25 per cent. of the regiment. The mortality has been low and most of the men have been able to return to duty.

Feb. 2nd.

THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

History and Formation of the Northumberland and Newcastle Medical Association.—The Amalgamation with the Newcastle Medical Ethical Society.

A FEW months ago the dissatisfaction of the Tyneside colliery surgeons reached an acute phase and consequently a desire to organise was manifested by various practitioners of the county of Northumberland. Close by, on the other side of the Tyne, at Gateshead, the parent association for this part of England, the union of the medical men of that town had given the example of useful and successful organisation. There was also at Newcastle a medical ethical society, but the idea then germinating was in favour of the more widespread organisation of a county rather than that of a mere local society. For this there was also an example close at hand in the County of Durham Medical Union. On the other hand, the latter society was naturally particularly anxious to see their nearest neighbours organise on similar lines to themselves. Indeed, this is how the movement is likely to spread. First the practitioners of a town form a union, then they find that their efforts are likely to miscarry because the practitioners in the outlying districts and surrounding country have not adopted the same principles and policy as themselves, consequently efforts are or will be made to bring the whole county into union. But hardly is this achieved than the county, as a unit, feels itself at a disadvantage if the neighbouring counties are not likewise organised, and thus the movement, to be thorough and absolutely effective, must spread from county to county till the medical men in all parts of the kingdom are united together for the maintenance of the same principles, the enforcement of the same means of action, and the defence of the same interests.

In Northumberland matters were brought to a head by difficulties which arose between the Backworth miners and the colliery surgeons of that district. The County of Durham Medical Union thought that the psychological moment had arrived when something might be done to crystallise the somewhat vague aspirations of the Northumberland medical practitioners. They consequently arranged to hold a meeting at the County Hotel, Newcastle-upon-Tyne, on August 23rd, 1900, and inserted advertisements in the local press inviting medical men to attend. The response was not very encouraging, for only a few practitioners were present. This, it should be noted, is what very generally happens. The first step is always the most difficult, and no experienced organiser would allow himself to be discouraged because the earlier efforts meet with but slight support. The meeting, though small, did good work. They determined to form a society and appointed Mr. Rutherford Morison as the President *pro tem.* They also selected a secretary, decided that a draft of rules should be prepared, and circulars were sent to all the practitioners inviting them to another meeting at which the union should be definitely constituted. This convocation differed from most of the other similar efforts that have been made, for it not only urged the advantages of organisation, but proposed immediate action and took the form of a *plébiscite*. With the circular there was a card which was to be returned to the secretary with answers to the following questions:—

1. Are you in favour of an increase of the rate of professional remuneration from 6*d.* to 9*d.* per fortnight for every adult workman?
2. Will you support a combined effort on the part of the medical profession to obtain this object?

The second meeting was held in the library of the Royal Infirmary on Sept. 6th and this time there was a good attendance. It was then definitely decided to form a medical union, and a committee was appointed carefully to examine and revise the proposed rules and to study the question of the remuneration for contract work according to the information that was now coming in from all parts of the country. Then a third and final meeting was held on Sept. 20th when the rules were adopted and the society was definitely constituted. The adoption of rules often causes much discussion and loss of time. In this case, however, the precedent established in the county of Durham served as a guide and it required hardly more than an hour to explain and vote upon the rules. Thus it will be seen that as experience extends the work of organisation becomes simplified. The dispute with the Backworth miners and the programme for future action was not so readily settled; but it was very generally felt that it was absolutely necessary to fix definitely a minimum rate of remuneration for colliery contracts; that not only must all members pledge themselves to observe this rule, but that it was necessary to create a fund to compensate those who might be victimised in this effort to improve the position of the profession. For the general purposes of the medical union each member was called upon to pay an annual subscription of half a guinea; but the indemnity fund, as it is called, is maintained by supplementary and voluntary subscriptions collected as the emergency arises, according to the necessities of the case and the means of the subscribers.

The next step was to effect an amalgamation with the Newcastle Medical Ethical Society, which had been in existence for more than a year and which had done excellent pioneer and educational work. This society was, however, limited to the town of Newcastle, and both organisations felt that it would be to their mutual advantage to amalgamate, and this was effected on Nov. 6th. The rules were slightly modified so as to comprise the principles of the two organisations and the amalgamation thus brought about is entitled the Northumberland and Newcastle Medical Association. Its object as the rules now stand is:—

To protect the interests of members of this association generally, but more particularly from unfair competition and from any attempts that may be made to induce or compel medical practitioners to accept insufficient remuneration for professional services. To establish and maintain minimum rates of payment for medical contract work in relation to all classes of workmen, members of friendly societies, sick and other clubs, lodges, insurance and other companies, and societies. To coöperate with and assist (when requested) the members of all approved local medical associations in carrying into effect any of the resolutions passed by such associations as may be approved by a majority of the members of this association in general meeting assembled.

On Dec. 20th another general meeting was held and a

standing sub-committee was then appointed to which all questions in relation to medical ethics might be referred. While this question of building up a constitution was progressing the more practical work of enrolling members was also actively pushed forward. In this the association, and indeed the profession generally, are much indebted to Mr. Rutherford Morison, who not only lent the influence of his name as president of the association, but has devoted a great amount of time and personal effort, not merely in presiding over the meetings, but in writing, telegraphing, and in travelling long distances so as to interview and persuade various practitioners who were hesitating to join and work with their colleagues in the profession. As one of the leading operating surgeons in the north of England Mr. Rutherford Morison has no personal interest to serve, and therefore his opinion acquires the weight rightly attached to all disinterested and altruistic endeavours. It is estimated that there are about 350 medical men in actual practice in the county of Northumberland and the town of Newcastle. In answer to circulars sent to all these practitioners and in response to the letters which had to be written to some of them and to the personal persuasion that in some instances had to be brought to bear 142 practitioners have joined the association and most of them have signed the following form:—

I desire to become a member of the Northumberland and Newcastle Medical Association and I undertake, if elected, to observe and conform to the rules, regulations, and decisions of the association. I agree also

(*a*) To accept no rate of remuneration for professional services lower than that approved by the association.

(*b*) Not to assist by consultation or otherwise (except in emergency) any practitioner in the counties of Newcastle-upon-Tyne or Northumberland who is declared by the above association to be opposed to the objects of the association.

At the time of the amalgamation the Newcastle Medical Ethical Society had 92 members, and the majority became members of the Northumberland and Newcastle Medical Association. But such union is not without its difficulties, for the interests and the position of the town practitioner differ widely from those of the rural districts, who, for the most part are colliery surgeons. It was at the commencement of 1899 that Dr. Alfred Cox, as secretary of the Gateshead Medical Association, urged that a similar organisation should be formed on the Newcastle side of the river Tyne. Dr. J. S. McCracken, agreeing, called an informal meeting of the Newcastle west-end practitioners in his own house. This was on Jan. 24th, 1899. 30 invitations had been sent out and no less than 23 practitioners attended. A committee was at once elected to organise a large meeting to which all the practitioners of Newcastle would be invited. This meeting was held at the Royal Infirmary on Feb. 15th following and was remarkable for its large attendance. It is estimated that there are about 140 practitioners in Newcastle and that quite 100 were present. Mr. J. Ackworth Angus was in the chair and the meeting unanimously and enthusiastically decided to form an association, to which they gave the title of "Ethical Society," and appointed a committee to frame a set of rules. These rules dealt with the future more than with the past—that is to say, their practical effect was to prevent the increase rather than to secure the abolition of old-established abuses. From the very beginning the association made a firm stand against the National Deposit Friendly Society. Of all such organisations this is probably the best, but it was new and if it gained a footing in the town then there would be yet another medical aid society to contend against. Also, there was a great objection to a lay society of this description dictating its terms even though these terms were fairly liberal. The National Deposit Friendly Society offered the Newcastle medical practitioners a 2*s*. 6*d*. fee for every other day and 1*s*. for the intermediary days. Thus if a patient required three visits in the course of six days there would be three fees of 2*s*. 6*d*. each, but if it was necessary to visit the patient every day then there would be three fees of 2*s*. 6*d*. each and three of 1*s*. each. This arrangement, it will be seen, is a great improvement on the system of weekly subscription paid whether well or ill. The medical attendant gets a much better fee, the society guarantees that the fee will be paid, and he is paid in due proportion to the work he does. Nevertheless, the Newcastle Medical Ethical Society decided to have nothing to do with the National Deposit Friendly Society. They would not allow the society to advertise any of their names and the only approach to a concession made was that of giving patients a detailed bill, which, of course, any patient has a right to claim.

While the Newcastle Medical Ethical Society was thus warning against the comparatively liberal terms of the National Deposit Friendly Society some of its members were taking the miserable allowance of 3*s*. 6*d*. per head per annum from members of the local medical aid association. There are also many friendly societies that do not pay more. But, worse still, it was now stated that at least one society intended to reduce the fee from 3*s*. 6*d*. to 3*s*. per annum and that both juvenile and female lodges were to be created. Consequently, and to meet this, the members of the Newcastle Medical Ethical Society decided that they would resign if any such alterations were made, and so that their position should not be occupied by others they resolved: "That no member accept a friendly society lodge at a less rate than was paid to the previous doctor"; and also, "that no juvenile lodge or juvenile members be accepted under 4*s*. per member per annum; also that no female lodge or member be accepted by any member of this society." It will be seen, therefore, that if little or nothing was done to remedy existing grievances the action taken was fairly energetic so as to prevent the extension of such abuses. The efforts made by the National Deposit Friendly Society and the Medical Aid Association to implant themselves in Newcastle were frustrated, as also the attempts of the friendly societies to lower the rate of subscription and to create female and juvenile lodges. One female lodge existed before this attempt at medical organisation; it still exists to-day; but its medical officer will resign when he receives a formal letter from the Northumberland and Newcastle Medical Association calling on him to do so. Up to the present the latter and more recent organisation has had its time absorbed dealing with the difficulties of the colliery surgeons, but at the next general meeting the interests of the town practitioners will be taken in hand. The Newcastle Medical Ethical Society, it has been seen, was constituted in February, 1899 and by amalgamating with the Northumberland Medical Association in November, 1900, ceased to exist as a separate body, and the joint organisations now took the title of the Northumberland and Newcastle Medical Association.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Overcrowding and Housing.

A CONFERENCE on the housing problem was held in Manchester on Feb. 9th. The chairman in a vigorous speech gave it as his opinion that "insanitary property should be condemned and compulsorily closed." A city councillor urged the local authorities "to vigorously use the powers they already possess under the Housing of the Working Classes Act, 1890." The president of the Trades Council said that "something of a definite character should be done." The conference was rich in such phrases which sound well and commit nobody. In April last a similar conference was held in a coöperative hall in this city, the only outcome of which was the passing of a resolution approving of the formation of a "Manchester, Salford, and District Housing Reform Council," and the bodies convening the meeting were asked to "appoint a council with power to add to their number." But amid all the vaporous rhetoric too often leading to nothing practical some facts were stated by Mrs. Clay, a lady well known for her work among the poor in the Hulme district, which show the pressing need for action in addition to talk. Speaking from an experience of nearly 20 years, she says that "the people are obliged to herd together without regard to health or decency." In one house with kitchen, scullery, and two bedrooms there are three families—six adults and eight children. In another house one room is the dwelling-place of a sandstone hawker, his wife, and three children. One of the children died and lay there for a week, the rest of the family living, eating, and sleeping in the room as usual. In another house with five rooms and a scullery there were 19 persons, and 16 in one of the same size close by. Not a stone's throw from these were two houses, each with one small bedroom, in which were two families, one of six and the other of seven children; the eldest of each family was a girl of 15 and 16 respectively. The family income of each was 18*s*. and the rent was 4*s*. As Mrs. Clay says, "habits of morality, decency, cleanliness

were, under such conditions, an utter impossibility." The difficulties in solving this problem are very great. Private enterprise is slow to come forward. The city council receives more abuse than thanks when it closes insanitary dwellings or clears them away. The builders of cottage property who sail close to the wind as regards the "building by-laws," and have reduced jerry-building to a fine art, are loudest in their denunciations of the corporation if they erect "barrack dwellings" or any other dwellings for the working classes, and say the corporation are becoming "speculative builders." But the corporation buildings in Ancoats appear to have brought down the death-rate in places by over 40 per cent. Our freedom, which is sometimes licence, would perhaps rebel against the proceedings said to be taken against dirty people and dirty houses in Berlin. There the former may be removed to a kind of workhouse in which they are detained while their houses are thoroughly cleansed and they themselves instructed in cleanly habits. A certain stratum of our population will always be filthy unless compelled to be clean, and is thus a constant danger to those around. Various schemes for spreading the people wider apart are at present in the "talked-of" stage, and may perhaps get no further.

Hospital Sunday.

The amount collected at the various churches and chapels on Feb. 10th.—Hospital Sunday—has not yet been publicly announced. It is stated that the various hospitals of Manchester and Salford had last year an aggregate deficit of £12,310. Still their work increases and some of them, rather than curtail it, are driven deeper into debt. In addition to the increased calls on the people in connexion with war and famine, which have no doubt diverted money that might have gone towards the support of the hospitals, another factor in the case has been the higher cost of coals and provisions, which has made hospital expenses heavier. The need, therefore, for large collections is manifest, but the experience of past years is not encouraging. In 1874 a sum of £6248 was collected, while last year it was only £3893. If all attending the various places of worship gave a trifle a larger sum than this should be obtained. But what is done by the great multitude who do not go to church?

Hospital for Skin Disease.

At the annual meeting of the Manchester and Salford Hospital for Skin Diseases held on Feb. 8th it was announced that a room was being built where the "light" treatment for skin diseases can be carried out. Towards this object the chairman, Mr. W. C. Jones, promised to defray the cost of the building and the necessary instruments to the extent of £500. Dr. H. G. Brooke visited Copenhagen last summer and was very favourably impressed by the excellent results of this treatment in the hands of Professor Finsen.

More Bacteria Beds.

The Rivers Committee of the Manchester City Council have resolved to extend their experiments with the bacteriological method of treating the sewage of the city. Hitherto they have had at Davyhulme two beds of half an acre each. They are now going to construct ten half-acre beds, which may be taken to mean that the two experimental beds have done their work satisfactorily. By gradually extending the bacterial beds the committee will be able to "test the efficiency of the system ere they commit the work absolutely to it." It is calculated that to deal with the whole of the sewage 46 acres of beds will be required. In the meantime this method is carried on alongside the chemical precipitation method, which has been in use for some years.

Typhus Fever in Ancoats.

At the meeting of the Manchester City Council on Feb. 6th Councillor Dr. C. H. Braddon moved the reception of a report from the medical officer of health respecting the recent outbreak of typhus fever in Ancoats. He gave an interesting sketch of a severe outbreak of the disease in the winter of 1862–3 when he had charge of the Workhouse Hospital in Bridge-street, together with the FeverHospital near Strangeways. Since that time he had not seen a case of typhus fever and "he believed that few medical men of the present generation had seen a case of real typhus." During that epidemic the late Sir William Roberts had a severe attack of the disease and nearly lost his life. Dr. Braddon said that care had been taken to disinfect every house in which the disease had been found, and beside the cases in hospital between 20 and 30 individuals were isolated at Clayton, where they were kept in quarantine. "The epidemic seemed likely to afford another instance of the vast importance of the sanitary powers which were exercised by local authorities in these days." In one house a man and two children were found "down with typhus," the wife having been previously taken to the hospital. Both parents died. The chairman of the sanitary committee said that the medical officer found the house locked and got in through the window, and that "the action of the medical officer of health in connexion with the outbreak was worthy of the highest praise."

Memorial to the late Professor Tom Jones.

The amount promised towards the memorial to the late Professor Tom Jones is already over £600. There has been no systematic canvassing, as it is desired that all donations should be the result of the personal wish of the givers to share in this tribute to the memory of a valued and lamented friend. The form of the memorial cannot be determined till the amount of the fund is known, but it may probably be decided that an exhibition or prize will be the most fitting mode of commemorating the work to which he devoted his life.

Feb. 19th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Precautions against Plague.

AT a meeting of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health held at Newport on Feb. 14th the area of the branch was defined to include the counties of Hereford, Gloucester, Somerset, Monmouth, Devon, Cornwall, the northern portion of Wiltshire, and the six South Wales counties. The next meeting of the branch will be held at Plymouth on April 11th. Dr. Edward Walford of Cardiff introduced a discussion upon the desirability of uniformity of action by port sanitary authorities with respect to methods of dealing with cholera, yellow fever, and plague under the Local Government Board order of Nov. 9th, 1896. In the course of this discussion it was made apparent that the only means of ascertaining which foreign ports were infected was by a careful study of the columns of the daily papers and that each port medical officer of health made out day by day his own list of infected ports and was guided by this list in deciding which vessels should come under the Board's regulations. Dr. D. S. Davies of Bristol pointed out that the plague regulations of 1896 were practically the cholera regulations of 1892, and that whereas cholera is a human disease the infection of plague may be transmitted by rats or fleas, and that although a ship may have left an infected port a considerable time beyond the incubation period of plague in the human being, yet there may still be danger from rat infection when the cargo is discharged. At Bristol every vessel from an infected port is kept 10 feet from the wharf, planks to the vessel are all taken up at night, and the ropes connecting the ship to the wharf are guarded with thin iron collars. At the close of the discussion it was resolved to request the council of the society to represent at an early date to the Local Government Board the urgent necessity for a revision of the existing plague regulations in view of the special charac eristics of plague, the method of its spread and introduction by infected animals, and the possible spread of the disease from one home port to another. Dr. J. Howard-Jones of Newport and Dr. W. H. Symons of Bath, at the close of the meeting gave very instructive details of the card system of tabulating statistics and general information which they have each had in operation for some time.

Isolation Hospital Accommodation in Carmarthenshire.

The county of Carmarthenshire is very ill provided with the means of isolating cases of infectious disease. Apparently there is no fever hospital in the entire county, which has an area of nearly 600,000 acres and a population of 150,000 people. The house committee of the Carmarthenshire Infirmary have drawn the attention of the Carmarthen Town Council to the importance of establishing a suitable hospital for the borough and at the last meeting of the council the medical officer of health and the borough surveyor were asked to report upon the whole question. As there is a population in the county

town of only a little over 10,000 persons it seems a pity that a scheme for the whole county, or at any rate for those districts immediately surrounding Carmarthen, should not be formulated.

Cardiff Police Surgeons.

For nearly 20 years Dr. Thomas Wallace has held the post of police surgeon to the Cardiff Corporation and, as already stated in this column on Jan. 26th, the watch committee recently decided to appoint three surgeons, allotting to each one a separate district. On Feb. 18th Dr. James Joseph Buist was elected to the central division, Mr. Marmaduke Pittard to the Grangetown division, and Mr. J. Llewellyn Treharne to the Roath division. Mr. Treharne, who is the surgeon to the prison at Cardiff, was elected chief surgeon and will be required to examine recruits, lunatics, &c. Dr. Wallace was a candidate for the central division. The duties of the police surgeons include attendance upon the constables and firemen at a fee of 4*s.* 6*d.* per annum for each man, a sum which is considered by many medical men in Cardiff to be quite inadequate to the services rendered.

Deaths under Chloroform.

Two deaths occurred in South Wales recently during the administration of chloroform. On Feb. 12th a married woman at Swansea, who was about to be operated upon at her own house for varicose veins, died under the anæsthetic, and on Feb. 15th a girl, 15 years of age, died under similar circumstances at the Cardiff Infirmary, where she had been attending as an out-patient. She had come on that day from her home to have her tonsils excised. In the latter case, although there were attempts at vomiting at the beginning of the administration of the anæsthetic, there was found on post-mortem examination to be no food in the stomach, and the other organs were in a normal condition.

Queen Victoria Convalescent Home, Bristol.

The convalescent home at Bristol, which was opened in November, 1899, by Queen Victoria and which was intended primarily to relieve the wards of the Royal Infirmary and of the General Hospital, has never, owing to lack of funds, been fully occupied. The treasurer of the home, Mr. P. Vaughan, has therefore offered to contribute the sum of £10,000 conditional upon an additional £20,000 being raised by the end of March next, and it is anticipated that this amount will enable the governors to make the fullest use of the institution. The citizens of Bristol are so noted for their philanthropy that there ought not to be any doubt as to the fulfilment of Mr. Vaughan's munificent offer.

Bath Eye Infirmary.

The annual meeting of the subscribers of the Bath Eye Infirmary was held on Feb. 11th. The medical report showed that the in-patients numbered 282, as compared with 268 in 1899, and that there were 2047 out-patients as against 2117 in the preceding year. The average period of residence of each in-patient was 12 days, and the daily cost for maintenance was 8¼*d.* The financial statement showed a favourable balance. The best thanks of the committee were awarded to Mr. W. M. Beaumont, the honorary medical officer.

Taunton and Somerset Hospital.

The annual meeting of the governors of the Taunton and Somerset Hospital was held on Feb. 14th, under the presidency of Mr. H. J. Badcock, J.P. The medical report stated that 846 in-patients had been admitted against 824 in the previous year. The daily average number of in-patients was 84·6 and the average duration of their stay was 32·7 days. The out-patients numbered 4191, as compared with 3968 in 1899. The President reminded the subscribers that the King was a life governor of the institution by virtue of a considerable contribution which His Majesty, when Prince of Wales, gave towards the Victoria Jubilee Nursing Institute in connexion with the hospital.

Conference upon Housing Reform.

One of the most gratifying features of the present agitation in favour of improved housing accommodation for the working classes is the activity which is being displayed in the direction of improvement by the leaders of the working classes themselves. On Feb. 16th a conference consisting of 191 representatives of trades unions and similar organisations was held at Bristol to consider what practical steps could be taken to secure housing reform in the west of England and south Wales. The members of the conference were drawn from an area extending from Swansea to Swindon and from Cheltenham to Exeter. Mr. W. Thompson, a member of the Richmond (Surrey) Town Council, gave an account of the municipal cottage dwellings which have been erected in Richmond. The Bristol corporation are now building 34 cottage houses, but it is not anticipated that the rentals received from them will, as at Richmond, be sufficient to pay the interest and repayments upon the capital outlay. All the speakers at the conference who were at all conversant with the subject urged the desirability of increasing the period for the repayment of loans contracted under Part III. of the Housing of the Working Classes Act, 1890, to at least 60 years.

Feb. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Preparations for a Small-pox Epidemic in Edinburgh.

EDINBURGH as yet presents a clean bill of health as far as small-pox is concerned. The public health authorities, however, have issued a circular to the medical men in the town recommending a general revaccination. They undertake to supply lymph to medical men free of charge, and to make an allowance of 2*s.* for every person successfully vaccinated. Cases of small-pox continue to occur in various towns near Glasgow. A few fresh cases have appeared in Dundee. The medical officer of health of Aberdeen reports to the town council that in the past month four cases of small-pox occurred within the city. The first two cases had been infected in Glasgow, and these led to the infection of two other cases. One was the case of a porter in the service of the sanitary department who, being only temporarily employed, had not been revaccinated, but who in the absence of the greater number of the staff on New Years' Day at the time of admission of the first case had inadvertently been permitted to assist in the removal of the infected clothing. The other case was that of an unvaccinated child in the hospital who lay in the scarlet fever ward nearest the small-pox pavilion, the ward and the pavilion being separated by from 40 to 50 yards of open space. This case appeared to have originated by aerial infection. In acknowledging the receipt of the report on this case the Local Government Board stated "that it seems to the Board to point to the necessity of entire structural and administrative severance of the treatment of small-pox from that of any other disease." The hospital authorities are advised that even substantial barricades, cutting off all communication or intercourse between pavilions in the same enclosure used for other diseases and pavilions used for small-pox in bulk, with complete administrative adjuncts and staff attached, do not prevent the invasion of small-pox.

Glasgow University.

The February meeting of the University Court was largely occupied by a discussion on the form in which the University accounts have been kept and presented. At a previous meeting Dr. D. C. McVail had adversely criticised the manner of keeping the accounts and had insisted that this was not in accordance with the terms of the legal ordinance. As a consequence the whole matter was remitted to the Finance Committee, which at the current meeting reported that "the accounts are in order and in proper form." The court adopted this decision though Dr. McVail maintained his position and entered his dissent. He took the same position in reference to a proposal to erect a room for the accommodation of students in the cloisters. The Finance Committee reported against this suggestion on the ground of the expense and the court agreed to their recommendation, Dr. McVail again dissenting.—The celebration of the ninth jubilee of the University which is to be held in June next is causing much activity in academic circles, and elaborate arrangements are being made to make the various ceremonies worthy of the event. A large number of representatives from home and foreign universities and scientific corporations have been invited, and the occasion is likely to be one of much interest. The fact that the International Exhibition is also to be held during the summer will make the city specially attractive for visitors.—The free lectures have been continued during the season and have as before secured large audiences.

University of St. Andrews.

The University Court has made the following appointments: Dr. Robert Thornton to be assistant in the department of medical jurisprudence and public health in the place

of Dr. Robert Mowat who has resigned; Mr. Sydney A. Kay, B.Sc., to be lecturer on chemistry; and Mr. R. C. Punett, B.A., to be lecturer on natural history. At the spring graduation ceremony the University is to follow the precedent recently established by the University of Edinburgh, the Senate having intimated its intention to confer the honorary degree of LL.D. upon two members of the gentler sex.

Handsome Gifts to Hospitals.

Mr. G. J. Kidston of the Clyde Shipping Company has given a donation of £5000 to the Glasgow Royal Infirmary, £5000 to the Western Infirmary, and £2500 to the Victoria Infirmary. These handsome sums are specially opportune at a time when, in common with other charities, the infirmaries are feeling the financial strain induced by the claims arising out of the South African war.

Small-pox in Glasgow.

The official bulletin issued on Feb. 18th leaves 387 persons under treatment in hospital. This is a reduction of 49 on the previous week's statement. New cases, however, continue to be admitted, but the dismissals far more than compensate for these. The new cases, too, show a diminishing rate, though the total is still considerable. During the fortnight ending Feb. 16th the admissions numbered 202, as compared with 350 during the previous fortnight. In his last report Dr. A. K. Chalmers announces that a careful record of the condition of the vaccination mark in all patients is being kept, and that the results will be dealt with in a subsequent report. The observations, it is satisfactory to know, are being made and recorded with critical minuteness, so that instead of a rough classification of "vaccinated" and "unvaccinated" details will be given of the size and character of the scar, the age of the patient, the severity of the attack, and the interval between its occurrence and the date of vaccination. An analysis of the small-pox records of the city during the last decade has recently been made by Dr. Robert S. Thomson. Dealing with the area of the vaccination scar in relation to the degree of protection afforded by the operation, it is shown that of all cases of small-pox occurring which presented a scar area of less than a quarter of a square inch 84 per cent. were discrete in type, but of those presenting over half a square inch of scar area 97 per cent. were of this character. In the first-class 14·6 per cent. of the patients died, while of the second only 1·6 per cent. were fatal cases. As to the value of revaccination, the experience of the small-pox hospital during the 10 years under review is very striking. In that time 595 persons not suffering from the disease were, by reason of their duties or for educational purposes, brought into contact with infection in the wards of the hospital, but not one who had been successfully revaccinated contracted the disease. The same truth is illustrated by the age distribution of the disease in the cases occurring during the past fortnight, which show that it is mainly on persons from 25 to 35 years of age that the incidence of the disease falls. 14 only of the 202 cases were in children under 10 years, and of these 11 were unvaccinated, six being babes varying in age from two weeks to seven months. All six were unvaccinated and five died, as did also an unvaccinated girl of two years. The age of the other unvaccinated children ranged from four to seven years. Of the three children who presented evidence of primary vaccination all were between six and eight years of age and the eruption in each case was sparse in quantity, although in all the vaccination mark was unsatisfactory, either by reason of the small size of the scar area or from absence of characteristic pitting of the surface. Of the deaths which occurred during the fortnight 17 were in unvaccinated persons; in two there was no evidence of vaccination though it was alleged to have been performed in infancy; and in four the marks were ill-defined The deaths occurring among vaccinated persons were as follows: under 30 years of age, two; under 35 years, two; under 40 years, six; under 55 years, two; and under 70 years, one. It is not stated whether in these cases revaccination had been performed.

Founders' Day at the University of Aberdeen.

In former times it was the custom of King's College to celebrate its founders' day, and sometimes the celebration was conjoined with the graduation ceremony. It is proposed by the Senatus of Aberdeen University to revive this laudable practice, but to give it a wider application. While the Colleges are two the University is one. It seems specially fitting therefore that Bishop Elphinstone and the Earl Marischal should be commemorated together. It is further the desire of the Senatus that the occasion be used as a great opportunity for bringing together graduates and alumni of the University from different parts of the country, as well as those from foreign lands who happen to be at home on furlough. The Senatus, accordingly, has resolved to celebrate the Founders' Day this year in the beginning of April, at the time of the graduation ceremony. The arrangements, which are being carried out by a committee of Senatus, contemplate the following: (1) a dinner (not exceeding, in expense, 7*s.* 6*d.* per head), open to all graduates and alumni, to be held on the evening immediately preceding the graduation ceremony—viz., Monday, April 8th; (2) a commemoration service in the University Chapel, on Graduation Day, at 10 A.M.; (3) the graduation ceremony in the Mitchell Hall, Marischal College, at 12 o'clock noon; (4) an evening reception in the same hall and adjoining rooms by invitation of the Senatus. The committee will feel obliged if those intending to be present will intimate the same, as early as possible, to Mr. D. R. Thom, secretary to the Senatus.

Feb. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Consultant Surgeons' Opinions on the War.

SIR WILLIAM THOMSON recently delivered a lecture at the Royal Dublin Society entitled "Dublin to Pretoria with the Irish Hospital." The lecture was very largely attended and evoked much interest. Sir William Thomson has kindly consented to repeat it at the Round Room, Rotunda, on Tuesday, Feb. 26th. Dr. Kendal Franks also recounted his experiences of the war at the annual meeting of the St. Patrick's Nurses' Home on Feb. 8th, when the chair was filled by his Grace the Archbishop, her Excellency the Countess Cadogan being present. As consulting surgeon to the forces in South Africa Dr. Franks furnished many interesting particulars about the war and strongly criticised the strictures of Mr. Burdett-Coutts on the hospital arrangements. He said that Lord Roberts on noticing them asked that a commission should be appointed at once to inquire into the matter. That commission included a set of men as entirely unprejudiced and impartial as it would be possible to obtain. The final paragraph of their report stated that there had been no breakdown in the hospital arrangements and that in no campaign had the sick and wounded been so well looked after. He thought that Mr. Burdett-Coutts's statements acquired more importance than they would otherwise have done from the fact that he bore a name which was synonymous with philanthropy, while, in fact, he "never moved a finger to relieve the sufferings he described." Dr. Franks went on to praise in strong terms the devotion and self-sacrifice of the medical men and nurses, whose conduct was, as he said, "simply splendid." His speech will well repay perusal and his allusions to the fortitude of the soldiers, reported in all the papers here, will be noted with interest and gratitude in a city and country where Dr. Franks made himself long ago well known and appreciated.

A Central Pathological Laboratory for Ireland.

In reference to the influential meeting and recommendation for a central pathological laboratory in connexion with the Lunatic Asylums of Ireland reported in THE LANCET of Feb. 9th it is satisfactory to note that the Dublin University Biological Association has proved active. In reply to a resolution, "That in the opinion of the Dublin University Biological Association it is desirable to establish a central laboratory for the Irish asylums devoted to the study of pathology in relation to nerves and mental disease," Sir D. Harrel, K.C.B., K.C.V.O., the under secretary to the Lord Lieutenant, by direction of His Excellency, wrote in acknowledgment of their letter and resolution.

Irish Memorial to the Queen.

A very large and representative meeting of the citizens of Dublin took place at the Mansion House on Feb. 17th, when a motion was proposed by the Lord Chief Justice and seconded by the Governor of the Bank of Ireland sympathising with the King on his irreparable loss by the death of the Queen. The motion was supported in eloquent speeches by Sir Christopher Nixon, the President of the

Royal College of Physicians of Ireland, and by Mr. T. Myles, President of the Royal College of Surgeons in Ireland.

Personation at Examinations.

A curious question has recently been referred to the Court for Crown Cases Reserved by Mr. Justice Kenny. A man was indicted at the Dublin Commission on Feb. 9th and charged with having fraudulently personated Robert F. Cooper at the preliminary examination of the Royal College of Physicians and Surgeons held on March 13th and 14th last. The jury found the accused guilty on the facts, but Mr. Bustie, K.C., raised the curious point that the prisoner has committed no offence known to the law. The case was then adjourned until the next Commission in April, and in the meantime the traverser was allowed to stand out on bail.

The Lurgan Workhouse Hospital.

As a result of an inquiry held by their inspector into certain charges preferred against nurses of the Lurgan Workhouse Hospital the Local Government Board have written to the guardians that in the particular case referred to (a child suffering from scarlet fever) Dr. J. S. Darling, the medical officer, was most attentive to the patient. They attribute any imperfection in the nursing and attendance to the fact that Dr. Darling's recommendations as to the strengthening of the medical and nursing staff were not adopted by the guardians. They say that neither of the nurses against whom complaints were made can, in the circumstances, be held responsible for any neglect or inattention. The Local Government Board say that the guardians do not appear to attach sufficient weight to the fact that the Lurgan Union Infirmary and fever hospitals are almost the only available hospitals for the ordinary surgical and medical cases of the important and increasing towns of Lurgan and Portadown, and therefore the requirements of an ordinary Poor-law infirmary and fever hospital are very far from being sufficient for the union of Lurgan. The guardians are accordingly requested to ask the medical officer to furnish a full report of what is requisite, in his opinion, for the adequate equipment of their infirmary and fever hospital, having regard to the important medical and surgical cases that are treated therein. Dr. Darling is to furnish his report to a committee and afterwards it is to be considered by a full meeting of the guardians.

Co. Down District Lunatic Asylum.

From a memorandum of the Government Inspector of Lunacy, Sir G. P. O'Farrell, I find he expresses approval of the treatment of the patients and of the general administration of the above institution. The medical officers are all warmly praised. The condition of the asylum as a whole must be considered very satisfactory, and as a proof that every care and economy were exercised in dealing with the funds of the institution it may be pointed out that notwithstanding the many improvements in the buildings and surroundings of the patients the actual capitation cost of maintenance is considerably less than it was 30 years ago.

Bazaar in the Students' Union, Queen's College, Belfast.

An entertainment took place in the Students' Union, Queen's College, Belfast, on Feb. 13th and 14th. It was organised and managed by the students, their aim being to get rid of a debt incurred in the working of the union. There were a bazaar and various side-shows and variety entertainments, and as a result the Students' Union is completely out of debt. It is hoped that with careful management further liabilities will not again occur. The union should be self-supporting.

Ulster Medical Society.

The fourth annual meeting of this society was held in the Museum, Belfast, on Feb. 14th, Professor W. H. Thompson, the President, being in the chair.—Dr. A. Fullerton showed a boy, aged six years, who, either as the result of injury received during his birth or from a subsequent epiphysitis had a Congenital Dislocation of the Right Hip. A radiogram of the affected parts was also shown.—Dr. Robert Campbell showed a child from whom two years previously he had Excised a very Large Occipital Cephalocele. A photograph of the original condition of the infant was also exhibited. Dr. Campbell also presented a radiogram of a case of Coxa Vara.—Dr. T. S. Kirk showed a Ruptured Kidney excised successfully from a boy in whom the accident occurred as the result of a fall from a ladder. He also gave a demonstration of a New Method of Wiring Oblique Fractures. By means of a rod of whalebone a piece of wire was slipped round the ends of the broken bone and tied in a clove-hitch.—Professor J. W. Byers showed two Ovarian Tumours successfully removed; one was a large unilocular cyst (which contained 12 pints of fluid) which simulated hydramnios, and the other was a very large universally adherent multilocular ovarian adenoma. The tumour had become so rotated that the part presenting when the peritoneal cavity was opened was the right broad ligament and tube covered with fresh lymph.—Dr. W. D. Donnan showed a Fœtus of an early date.—Professor J. A. Lindsay showed a specimen of Cancer of the Root of the Lungs. Professor J. A. Lindsay read a paper upon Rare Cases of Pulmonary Disease, including (1) three illustrative cases of malignant disease of the lungs (one with purulent infiltration, a second which simulated phthisis, and a third with very obscure physical signs); (2) a case of pyo-pneumothorax; (3) a case of bronchopleural fistula; (4) a case of plastic bronchitis; (5) a case of double pneumonia with delay of crisis to the twentieth day; and (6) a case of phthisis where signs and symptoms disappeared for seven years and then recurred.—In the subsequent discussion the following took part: Professor W. Whitla, Dr. P. Redfern, Dr. J. S. Morrow, Mr. R. Hall, Dr. R. W. Leslie, Dr. W. Calwell, Dr. D. M'Donnell, Professor Sinclair, and Professor Byers.

Curious Prosecution under the Public Health Act.

Last week the sanitary authority at Cork applied for an order at the police-court for the removal of the body of a child to the morgue and for its burial within three hours. The circumstances of the case were remarkable. The child had died a week previously and the body lay coffined in the room occupied by the mother who was ill. The father of the child is a soldier serving out in South Africa, and, despite the protestations of her friends, the unfortunate mother declined to allow their little one to be buried, and signified her intention to keep the coffin in the room till the father returned in order that he might have the satisfaction of seeing his dead child. The magistrates granted the order sought and the interment was duly carried out.

Feb. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Paris.

ALTHOUGH the recent epidemic of small-pox in Paris, which was caused in the main by the influx of strangers for the Exhibition, is not such a general object of conversation as formerly, yet it must not be considered as being at an end. During the last week of January there were registered 12 deaths from small-pox, while 84 fresh cases were notified by the medical officer belonging to the health department of the Prefecture. These medical men are far from strict in notifying cases, for although such notifications may be useful they are afraid of displeasing fidgety patients. In the last week but one of January there were only six deaths notified. It is the duty of everyone to be revaccinated if it has not been already done, but now that the scare has passed people are getting very careless, and to escape this little operation they vie with one another in finding out reasons to show its uselessness. Among domestic servants, for instance, the objection is simply unreasoning pigheadedness; among masters and mistresses it either takes the form of smiling scepticism, or they say, "I was revaccinated so many years ago; I have had small-pox." At a meeting of the Academy of Medicine the venerable M. Hervieux opened an important debate on the question and showed very clearly that the matter of revaccination should be vigorously pushed, that the immunity conferred by a former revaccination lasts but for an uncertain period, and that even an attack of small-pox, contrary to the generally received opinion, is not an absolute protection. Certainly it is very uncommon to find persons who have had small-pox twice, but a certain number are known besides the classical instances such as that of the Milan hospital attendant who had four attacks. During an epidemic, in M. Hervieux's view, even those who have had small-pox should be vaccinated. While upon this point M. Hervieux thought it well to protest strongly against the popular and not altogether

disinterested opinion that the lymph supplied gratuitously by the Academy of Medicine and collected under special surveillance of a committee appointed for the purpose, was inert. M. Empis associated himself with this protest and expressed regret that the obloquy thrown upon the lymph of the Academy should have been echoed even in some medical journals. Speaking for himself he had performed 200 revaccinations with this lymph and had only failed in the case of certain adults doubtless because they were already immune from a previous vaccination. M. Kelsch declared that the value of a vaccine could not be estimated from one series of vaccinations, as success depended upon so many different factors. An identical vaccine taken at Val de Grâce had given in the hands of one operator 7 per cent. of successes and in the hands of another operator 50 per cent. Finally, on the motion of M. Colin the Academy decided to distribute a new appeal among the population of Paris to impress them with the urgent necessity of submitting to revaccination.

Tokelau.

M. Jeanselme has sent from Indo-China a very interesting report upon "tokelau," a disease of the skin peculiar to the East, which is widely spread and which is characterised in addition to itching and the formation of desquamating patches of a dirty-yellow colour, by the appearance of curious patterns of a geometrical regularity. These patterns take the shape of intersecting circles which cover the patient with all kinds of bizarre designs. Tokelau only grows on the naked skin and does not affect the hairy skin. According to M. Jeanselme the disease is due, not as was formerly supposed to a trychophytosis of the tinea imbricata type, but to an aspergillosis. There is an abundant mycelial network to be found in the scales of tokelau, producing sporiferous branches of a yellow colour which give rise to the pale-coloured patterns so characteristic of this disease.

"Stomatite Erucique."

At the recent meeting of the Society of Biology M. Artault gave an account of a curious form of stomatitis which he proposed to call "stomatite erucique," the origin of which had been hitherto unknown. It is, however, now known to be caused by eating fruits which have been in contact with the nests of certain caterpillars possessing an urticating property. The inflammation attacks the mucous membrane of the mouth, the lips, the gums, the cheeks, and the palate. The cause is the irritating hairs and secretions which the caterpillars leave in their nests. The disease, as a rule, attacks children who eat fruits which are taken into the mouth whole, such as cherries and gooseberries, and it is hardly ever seen except during the months of May and June, especially in dry years. A mouth-wash composed of tincture of "myrtille"[1] generally cures the complaint very easily.

Glycosuria and Dyspeptic Diabetes.

A very notable event was the reading of a paper before the Academy of Medicine by M. Albert Robin upon dyspeptic diabetes. The beautiful researches in applied clinical chemistry at which M. Robin has worked for so many years have upset all preconceived ideas in the pathogeny of gastric chemistry, in which department up to now the ideas of Germain Sée and of Bouchard have reigned supreme. The researches of M. Robin have made known to us a special form of glycosuria depending upon a reflex excitation of the liver by the arrival in the intestines of a very acid gastric product of digestion. This renders the biliary secretion much more active and increases the formation of sugar. What is very important is that this form of diabetes is absolutely curable, for as it depends upon a fault of digestion it suffices to get rid of this fault to cure glycosuria. Simple glycosuria is found in 5 per cent. of cases of hypersthenic dyspepsia. It takes an irregular form and is always slight, the quantity of sugar varying from 50 centigrammes to six grammes per litre; it is found in the urine of digestion but is absent from that of fasting, and sometimes it is found in company with the albuminuria of digestion. In these patients nutrition is marked by an exaggeration of exchanges, by a deficient assimilation of nitrogen, and by an over-excitement of the nervous system. The stomach is often distended, the liver hypertrophied, and there is also a condition of hyperchlorhydria. The patients suffer from vertigo, phosphaturia, and various skin affections, such as hyperidrosis. There are, in addition, affections of sight and hearing. Glycosuria may be either consecutive or previous to dyspepsia. This distinction is important, for dyspeptic diabetes can be cured by treating the dyspepsia, whereas ordinary diabetes resists all treatment. Diabetes is not a disease characterised by a slowness of nutrition, but rather by a too quick performance of nutrition and a hyperaction of the liver. Medicines which excite nutrition aggravate diabetes, while medicines which diminish nutrition improve the diabetes. Glycosuria always points to over-activity of the liver. It bears a definite relation to hypersthenic dyspepsia. Over-excitation of the liver, at first occasional, becomes permanent and so a real diabetes of gastric origin is set up. Dyspeptic glycosuria can be cured by treatment of the dyspepsia, the administration of alkalies after meals being generally sufficient. In more severe cases a strict milk diet is advisable, although this diet is harmful in cases of true diabetes. When dyspeptic diabetes is established the sugar in the diet must first be reduced and then the treatment of the dyspepsia undertaken.

Three New Hospitals.

The buildings and interior fittings of three new hospitals—respectively in the Rue Etex, the Rue Michel Bizot, and the Place Danube—are finished. The opening will take place about April 1st. The three hospitals are for sick children and will take the place of the old Trousseau Hospital in the Faubourg Saint-Antoine. The one in the Rue Etex is the Bretonneau Hospital and will contain 60 medical beds, 74 surgical beds, 84 beds for infectious cases, and 16 beds for cases in which the diagnosis is uncertain. The members of the staff are Dr. Seveste, Dr. Josias, and Dr. Felizet. The building in the Rue Michel Bizot is the new Trousseau Hospital. The beds are allotted as in the Bretonneau Hospital, with the exception that those for doubtful cases will number 19 instead of 16. The staff are Dr. Netter, Dr. Louis Guinon, and Dr. Kirmisson. The third building, in the Place Danube, is the new Herold Hospital, the staff of which are Dr. Barbier, Dr. Jeanselme, and Dr. Albarran. Here there are 56 medical beds, 64 surgical beds, 84 beds for infectious cases, and 16 beds for doubtful cases. All three buildings are erected and fitted according to the very latest demands of modern hygiene. Although not strictly speaking a new hospital I may mention that the Hertford Hospital has just been formally reopened. Founded in 1871 by the late Sir Richard Wallace it was for many years under the management of a committee appointed by him. In 1891 he offered it to the British Government and at the same time promised to endow it. His death took place before the transfer could be carried out. Lady Wallace, however, carried out her husband's wishes and provided the necessary endowment. The transfer was formally effected last year and a committee was appointed for its management. This committee considered it necessary that the building should be repaired and altered in order to bring it up to modern sanitary requirements, and it was accordingly closed in August, 1900. The opening took place on Feb. 18th, the Hon. Michael Herbert (chairman of the committee) and Mr. H. Austin Lee (of the British Embassy) receiving the guests on behalf of the Ambassador, Sir E. Monson, who was unfortunately prevented by illness from being present.

Feb. 19th.

[1] Myrtille is the vaccinium myrtillus or blaeberry, not the common myrtle which is "myrte."

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Blind in Switzerland

STATISTICS on the blind are few and far between in this country and therefore the report which Dr. Laurenz Paly of Entlebuch publishes on the subject is of value. The number in 1895 amounted to 2107 persons, of whom 1783 had undergone a medical examination; in 1870 the number was 2032, or a percentage of 0·072 of the population, compared with a percentage of 0·076 in 1895. The comparative number of males and females were 52·6 to 47·4 in 1895. Dr. Paly divides the blind into the four following classes (I put the percentage in parentheses): (1) Visus = 0, absolute amaurosis (57·7 per cent.); (2) visus = $\frac{1}{6}$, distinguishing light and darkness (24·2 per cent.); (3) able to count fingers at 0·3 metre or about one English foot (10·4 per cent.); and (4) able to count fingers at one metre (5·1 per cent.). In 2·4 per cent. the examination failed to give the necessary details. In a percentage of 6·8 of the cases

blindness was congenital, in 93·2 it was acquired. Of these, 66·9 per cent. could be referred to primary disease of the eye, 12·7 per cent. to traumatic influences, and 13·5 per cent. to general diseases.

The Therapeutics of Urotropine.

Dr. F. Suter of Basle reports on his experiences with urotropine, which was originally recommended by Nicolaier for vesical catarrh. It is an antiseptic compound produced by the action of formaldehyde on ammonia; it is easily soluble in water and ought to be taken on an empty stomach, as the acid reaction of the stomach decomposes it rapidly, when part is absorbed and part excreted in the urine. It slowly decomposes in the bladder only in urine of acid reaction, not in neutral or alkaline. It decomposes perhaps more rapidly in the kidneys, as it acts very promptly in cases of alkaline decomposition of the contents of the bladder. Five or 10 milligrammes of formaldehyde have the same action on three ounces of urine as half a gramme of urotropine, and yet experiments and clinical use prove its antiseptic action even in these small doses. The action on different bacteria varies but a little; bacilli coli communis and streptococci seem most resistant. Dr. Suter made experiments with the following medicines administered at night whilst the urine passed first in the morning was examined: benzoic acid 10 grains, boric acid 15 grains, salol 15 grains and 45 grains, and urotropine 15 grains. The development of decomposition was retarded by several days only by the strong dose of salol and by urotropine. Its efficacy being thus proved its high cost is to be regretted, for this limits its exhibition. It is to be recommended in cases of surgical interference (even catheterism); in bacteriuria, especially after enteric fever, where it occurs in from 20 to 30 per cent. of all cases; and in cystitis, as an aid to local treatment, which often is necessary. It is of little value in pyonephritis, gonorrhœal cystitis, or tuberculosis of the kidney; it is no panacea for all cases of cystitis, but acts best in ammonia decomposition. It should also be used in disease of the prostate gland with residuary urine and cases of stricture with partial retention, where it is a decided improvement on salol. Doses of from 15 to 25 grains per diem can be given for weeks in succession. Such are Dr. Suter's conclusions.

Attendance at Swiss Universities.

The number of medical students is decidedly on the increase without any obvious reason in the way of demand. The number of medical students for the winter term 1900–1901 amounts to 1375, thus distributed among the separate universities: Basle 145, Bern 388, Geneva 357, Lausanne 183, and Zürich 302. The number of women studying medicine in Switzerland has greatly increased, especially of foreign women. Of these the Russian female students are the most numerous, comprising 47 per cent. of the whole. Only 21 are of Swiss nationality.

Zürich, Feb. 13th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Death of the Queen.

WHEN the news arrived in Canada that the Queen was no more it came to the medical colleges in the midst of lectures which were immediately stopped. On the afternoon of Feb 2nd a students' parade took place in Montreal from McGill College to the Queen's statue, headed by four students bearing on their shoulders a large cushion of natural carnations in the form of the Star of the Order of the Garter which was deposited at the feet of the statue. The entire medical faculty accompanied them.

Blindness decreasing in Ontario.

The annual reports upon the Ontario Institutions for the education of the Deat and Dumb at Belleville and of the Blind at Brantford have just been published. They cover the year ending Sept. 30th, 1900. At the Institution for the Deaf and Dumb the number of pupils in attendance was 152 males and 130 females, a total of 282, which is about the average in recent years. Since the establishment of this institution 30 years ago 1187 children have been treated. At the Institution for the Blind there were 113 pupils in attendance, 61 males and 52 females, which number was less than for the preceding year. Referring to the causes which led to the decrease Principal Dymond attributed it to the eye infirmary attached to almost every hospital in the province, thus affording a means of easy and inexpensive relief. He thinks that the eyesight of one-fourth of the young people under his charge might have been saved had prompt precautions been taken in infancy and treatment by a skilled oculist been then secured at one of these infirmaries. Greater watchfulness on the part of the immigration officials is also a contributing feature to the decrease.

New Scholarship at Queen's College, Kingston.

The medical faculty of Queen's College have decided to found a new scholarship in medicine in commemoration of Dr. Fife Fowler, dean of the faculty, who recently retired from the professorship of medicine and who for more than 46 years has been in active work in the service of the college. This scholarship will be known as the Dean Fowler Scholarship, and the sum of $10 000 will be immediately raised amongst the graduates of Queen's College throughout the United States and Canada. The medical faculty have already amongst themselves contributed a good sum. In addition to this the faculty are further raising amongst themselves $10,000, which will be expended in enlarging and extending the medical buildings of Queen's College. To this sum no outsider will be asked to contribute.

The late Dr. C. W. Purdy.

Canada and Queen's have recently lost a distinguished son by the death of Dr. Charles W. Purdy, a well-known authority on uranalysis and urinary diagnosis. He was born at Collins Bay, Frontenac County, Ontario, on June 18th, 1846. His literary course was taken out at Victoria College, then situated at Coburg, and his medical degree was received from Queen's in 1866. He practised in the county of Hastings for a year when he moved to Chicago. His alma mater conferred upon him a Fellowship and the degree of LL.D.

The Death-rate of Montreal for 1900.

There were 7351 deaths in Montreal in the year 1900. This was the largest number which has been recorded since 1885, when 7825 deaths occurred; but since that year the city has taken a big leap in population. In 1885 the death-rate per 1000 was 4691 and in 1900 it was 25·47. In other recent years the rate was as follows:—1894, 27·27; 1895, 24·81; 1896, 21·92; 1897, 22·48; 1898, 20·66; and 1899, 24·51.

The Victorian Order of Nurses.

The executive council of the board of governors of the Victorian Order of Nurses recently met in the city of Ottawa, Her Excellency the Countess of Minto and the Countess of Antrim being present. Miss McLeod, the superintendent, presented her monthly report. In Montreal four of the six nurses had been on duty during the month of December and 43 patients had been attended by them. They paid 570 visits and received $98 in fees. At present there are 38 nurses in the Victorian Order in Canada. They have to serve six months on trial before being finally accepted and they receive $15 per month for that time.

The Medical Alliance of America.

Something over a year ago an organisation with the above title secured a charter from the Dominion Government, and at once proceeded to exploit the profession of medicine in Montreal and elsewhere. When the alliance was seeking powers from the Canadian Parliament its methods and its purposes received pretty severe criticism in the pages of the *Montreal Medical Journal*, but for some reason or other this was not followed up by any of the other medical journals in Canada, so that when the agents of the alliance some few weeks ago commenced operations in the city of Toronto their name was quite new to the medical profession there. The objects of this alliance are to insure people against medical bills, to insure practitioners against bad accounts, and to insure financial profit to the company. Medical men and the laity are solicited to become members of the alliance at the rate of 15 cents a month, or a man with a family can become a member at the rate of 10 cents per month per member of family. At the end of 10 years the member of the alliance is handed back all the money he has paid into it, and during all that time he has had his medical attendance for nothing. The advantage to the physician of becoming a member of this alliance, from the standpoint of the company, is that the company will pay his bills and that he will have no more bad debts to collect.

The alliance is receiving the cold shoulder from the medical profession in Toronto.

Royal Victoria Hospital, Montreal.

The governors of the Royal Victoria Hospital held their annual meeting in the last week of January. The superintendent's report showed that during the year 1900 there had been 2619 patients admitted to the hospital. Of these 1469 were free patients, 741 were public ward patients at 50 cents per day, and 409 were private patients. The death-rate for the year had been 4·95 per cent., or if those dying within 48 hours after admission be deducted, 3·83 per cent. The total cost per day per patient was $1.47 as against $1.55 in 1899. The income for the year was $129,570.34, while the ordinary expenditure amounted to $99,208.62, leaving a balance of $30,361 72 which will be applied towards the cost of the new out-patient department.

Hospital for Sick Children, Toronto.

The report of this institution for the year ending Sept. 30th, 1900, shows that the hospital has cared for over 40,000 sick children of the province during the past 25 years and that the debt of $19,000 has almost entirely disappeared. The daily average of patients in the previous year was 101; during the past year it has been 111. During the past year 5776 patients have been treated. Of these 767 were in-patients, an increase of 97 over 1899, and 5009 were out-patients, an increase of 734 over the previous year. On Toronto island, overlooking Lake Ontario, is what might be called the summer residence of this institution. It is known as the Lakeside Home for Little Children and is a well-equipped sanatorium with accommodation for 150 children and 20 nurses.

Toronto, Feb. 9th.

Obituary.

MAX VON PETTENKOFER.

(FROM OUR BERLIN CORRESPONDENT.)

PROFESSOR VON PETTENKOFER, the founder of scientific hygiene, and one of the veterans of medical science in Germany, died in Munich on Feb. 10th. The circumstances of his decease were very tragic, for he committed suicide while in a state of mental depression induced by dread of losing his reason. He had reached an advanced age, being born in 1818 at Lichtenheim in Bavaria. He completed the curricula both of a chemical and also of a medical student at Munich, receiving the diploma of a chemist and the degree of M.D. from that university. He was in course of time appointed assistant chemist to the Royal Mint at Munich and while holding this position made a series of researches both in theoretical and practical chemistry. As early as 1850 he turned his attention to hygienic questions, a subject which attracted him on account of the amount of illness existing in Munich, which was formerly one of the most unhealthy towns, not only of Germany, but of the whole continent. Enteric fever was prevalent there nearly the whole year round and cholera, when appearing in Munich, was of the most malignant character. He made enteric fever his special study and discovered that there was a definite connexion between this disease and the subsoil water. According to his theory enteric fever became prevalent when the subsoil water was low. This theory he maintained for a long time, till the new bacteriological era in hygiene, inaugurated by the researches of Professor Koch and his disciples, began; although he was fully aware of the great importance of bacteriology in hygienic questions he could never be convinced that pathogenic bacteria were the only causes of epidemic diseases and that the object of hygiene was to get rid of them. In the beginning of the bacteriological era the hygienists of Germany were really divided into two different parties, the Pettenkofer school and the Koch school; in course of time a compromise took place between the "contagionists" and the "localists" as it was recognised that the two theories were not contradictory. It may be remembered that Professor von Pettenkofer in order to prove the innocuousness of bacteria went so far as to swallow a culture of cholera bacilli. His health did not suffer and it is now known under what circumstances this experiment may be safely performed and that it is quite inconclusive as evidence that these bacteria are harmless. At the time, however, it was believed to be a valuable argument against Professor Koch's theory. Professor von Pettenkofer took care that his researches should bear fruit in a practical sense by leading to hygienic improvements in Munich. By his advice sewers were constructed and the water-supply was regulated in so satisfactory a manner that Munich is at present one of the healthiest towns in Germany. The malignant form of enteric fever formerly so characteristic of Munich has disappeared and the sporadic cases which occur are neither more numerous nor more severe than elsewhere. In addition to his work on enteric fever Professor von Pettenkofer made numerous researches on ventilation and heating, on the chemical and physical qualities of the soil, on food, and on respiration. His researches on the phenomena of respiration were of fundamental importance. He worked at them in conjunction with Professor Voit by the aid of a special apparatus which was a gift from the late King of Bavaria and which enabled experiments to be made on the human subject. He was the first who introduced exact scientific methods into hygienic questions and who treated hygiene from an experimental point of view. It was through him that hygiene has been raised in public opinion to an equality with the older branches of medicine and that the State authorities have given it practical recognition by appointing professors of hygiene in every university of Germany. Although some of his views have been superseded by more recent researches he will ever be regarded as the leader of the modern developments of hygiene. The announcement of his melancholy death has therefore caused great sorrow, and the newspapers are unanimous in expressing the opinion that in him Germany has lost one of the greatest of her sons.

BARON ALFRED RUGG, L.R.C.P. LOND., M.R.C.S. ENG.

BY the death of Mr. Baron Alfred Rugg on Feb. 11th Wood-green has sustained a serious loss. Of handsome and distinguished presence Mr. Rugg was a well-known figure in the district and enjoyed the esteem and confidence both of his professional colleagues and of the public.

His medical education was received at University College. In 1868 he took the diploma of M.R.C.S. Eng. and in 1869 that of L.R.C.P. Lond., after which he acted as medical officer at Bournemouth General Dispensary and at Earlswood Asylum. He joined the late Mr. Basil Ringrose as a partner in 1875, and since that date his life was spent in Wood-green, a place which has developed from a picturesque village into a populous suburb of North London. Mr. Rugg was surgeon to the Oddfellows and Foresters and to the Great Northern Railway; he was on the staff of the Wood-green Cottage Hospital and acted as medical referee to several insurance societies. He died at the age of 53 years from pleurisy and pneumonia after only a few days' illness and was buried at Paddington Cemetery.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ritter von Hochberger, who was the *doyen* of Carlsbad physicians, having attained the age of 92 years. He was, however, able only two years ago to take an active part in a medical congress.—Dr Johann Natterer, a Vienna medical practitioner, whose scientific work in the domain of experimental physics—e.g., the liquefaction of gases—was of a quite uncommon order for a man engaged in active medical practice. He was 80 years of age.—Dr. Victor Pashutin, Professor of Pathology in the St. Petersburg Military Medical Academy. His researches on the physiology of the nervous system and on medical chemistry, together with his text-book on general pathology, marked him as a worthy representative of Russian medical science. He was 55 years of age.

HEALTH OF TORQUAY.—Mr. P. Q. Karkeek, the medical officer of health of Torquay, in his annual report for 1900 states that the birth-rate was 15·5 per 1000 and the death-rate was 13·6 per 1000. There were 29 deaths from cancer. During the year 40 cases had been admitted to the sanatorium for infectious diseases. Mr. Karkeek reports that places where ice-creams were manufactured had been inspected and improvements made, and he adds that, speaking generally, the manufacture of penny ices is not carried on under satisfactory conditions.

Medical News.

UNIVERSITY OF LONDON.—At the Intermediate Examination in Medicine held in January the following candidates were successful:—

ENTIRE EXAMINATION.

First Division.—Olive Muriel Elgood, London School of Medicine for Women; Archibald M. Henry Gray, University College; Leonard Gregory Parsons, University of Birmingham; and John Bart Rous, St. Mary's Hospital.

Second Division.—Edwin Lancelot Ash, St. Mary's Hospital; Gerald Eade Bellamy, Charing-cross Hospital; William Brown Clark, King's College; Helen Mary Collen, London School of Medicine for Women; Ernest Harold Drinkwater, University College, Liverpool; John Ferguson, St. Bartholomew's Hospital; Peter Gifford Foulkes, Middlesex Hospital; Jessie Josephine Francis, London School of Medicine for Women; A. Augustus Russell Green, University of Birmingham; Harold Axel Haig and Geoffrey Seccombe Hett, University College; Bernard Higham, St. Thomas's Hospital; William Algernon Louis Holland, University of Birmingham; Richard Holtby, St. Bartholomew's Hospital; Catherine Mary Ironside, London School of Medicine and Royal Free Hospital; Cecil Lionel Lakin, Charing-cross Hospital; Jessie Lamb, London School of Medicine and Royal Free Hospital; Charles Hugh Latham, St. Thomas's Hospital; Norman Macfadyen, St. Bartholomew's Hospital; James Alexander Milne, London Hospital; Clifford Arthur Moore, University College, Bristol; James Cecil Mottram, University College; Percy Alfred Peall, Guy's Hospital; Kate Anne Platt, London School of Medicine and Royal Free Hospital; Ireton George Pritchard, King's College; Charles Michael Roberts, St. Thomas's Hospital; Frank Herbert Rotherham, Cooke's School of Anatomy and Charing-cross and London Hospitals; Charles Russ, St. Mary's Hospital; Francis William Schofield, Owens College and Manchester Royal Infirmary; Henry Gates Sievwright, University College, Cardiff; Herbert Douglas Smart, Guy's Hospital; Annie Broomhall Thin, London School of Medicine, King's College, and Birkbeck Institution; Asa Claude Ali van Buren, St. Bartholomew's Hospital, King's College, and Cooke's School of Anatomy; Hugh Watts, Guy's Hospital; and Ada Miles Whitlock, London School of Medicine and Royal Free Hospital.

EXCLUDING PHYSIOLOGY.

Second Division.—Alice Marian Benham, London School of Medicine for Women; Christian Constance Bernard, London School of Medicine and Royal Free Hospital; Margaret Lucy A. Boileau, London School of Medicine for Women; Percy Charles Bushnell, St. Thomas's Hospital; William Henchman Cole and Charles Henry Dawe, Guy's Hospital; Mabel Emily Gates, London School of Medicine and Royal Free Hospital; George Francis Innes Harkness, University College; William Charles Frederick Harland, St. Bartholomew's Hospital; Bernard Hart, University College; Horace Bryden Hill, St. Bartholomew's Hospital; William Stanley Hughes, University College, Cardiff; Henry Arthur Kellond-Knight, St. Bartholomew's Hospital; Kate Knowles, London School of Medicine for Women; Anthony Richard Neligan, St. Bartholomew's Hospital; John Jekyll Rainforth, London Hospital; Charles Chapman Rushton, Owens and University Colleges; Isabel Gertrude Sexton, London School of Medicine and Royal Free Hospital; John Kendall Syms, University College; and Margaret Cordelia Vivian, London School of Medicine and Royal Free Hospital.

PHYSIOLOGY ONLY.

First Division.—Ernest William Charles Bradfield, St. Mary's Hospital; Desborough Brodie, St. George's Hospital; Anne Fenton Cleaver, London School of Medicine and Royal Free Hospital; Philip Claude Tresilian Davy, University College; John Jones, London Hospital; Beatrice Mary Kidd, London School of Medicine for Women; Edward Bertram Smith, St. Bartholomew's Hospital; Emily Gertrude Stuart, London School of Medicine and Royal Free Hospital; Robert James Waugh and Edward Colston Williams, St. Bartholomew's Hospital; and Henrietta Leila D. Williams, London School of Medicine for Women.

Second Division.—George Cuthbert Adeney, St. Thomas's Hospital; Walter Ball, Westminster Hospital; Jeannette Rachel De Pass and Ruby Ellen Glanville, London School of Medicine for Women; Herbert Myer Goldstein, Guy's Hospital; Ida Margaret Guillaume, London School of Medicine and King's College; Herbert Stanley Jones, Guy's Hospital; William Wilson Nock, Mason University College; Charles Derwent Pye-Smith, Guy's Hospital; John Noel Sergeant, St. Thomas's Hospital; Herbert Bartlett Simpson and Malcolm William Stewart Smith, University College; James Batson Stephens, St. Mary's Hospital; Ernest William Strange, Guy's Hospital; Robert A. Slater Sunderland, St. Bartholomew's Hospital; Louisa Graham Thacker, London School of Medicine and Royal Free Hospital; Edith Eleanor Tucker, London School of Medicine for Women; Frederick Robert Elliston Wright, St. Thomas's Hospital; and Walter Perceval Yetts, St. Bartholomew's Hospital.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the first examination of the board at the January meeting of the examiners in the subjects indicated:—

Chemistry.—Edward Bailey Aylward, Parwatiprarad Vishvanath Bratt, and Rowland Alessandro Bowling, St. Bartholomew's Hospital; Bertram Frend Bartlett, University College, London; Arthur Ellis Blythman, University College, Sheffield; John Bryan and Francis Garland Collins, London Hospital; Laurence Henry Burner, Guy's Hospital; William Cook, Mason University College, Birmingham; Clifford Pendrill Charles and Percival Alfred Dingle, St. Bartholomew's Hospital; Frederick Spencer Davies, St. Thomas's Hospital; Alfred Dinnis and Harold William Farebrother, Charing Cross Hospital; Richard Vernon Favell, William Reginald Favell, and William Edward Lindsey Fowler, St. Bartholomew's Hospital; Ira Rose Fearn, Guy's Hospital; George Edward Ferguson and Frederick William Hobbs, St. Mary's Hospital; William James Fletcher, Owens College, Manchester; Hector Lionel Howell, Charing Cross Hospital; Alfred John Hopkinson Iles, St. Thomas's Hospital; Robert Rutson James, St. George's Hospital; James Charles Robert Lind, University College, London; Cecil Henry Gustav Luxmoore, St. Mary's Hospital; Malcolm Leckie, Rowland Phillip Lewis, and John Orrett Musson, Guy's Hospital; Walter Gerald Loughborough and James Eustace Radclyffe McDonagh, St. Bartholomew's Hospital; Douglas Catterall Leyland Orton; Owens College, Manchester, and the Municipal Technical School, Oldham; Benjamin James Phillips, Surgeons' Hall, Edinburgh, and University College of South Wales, Cardiff; Walter Reeve and Edwin Walter Routley, Guy's Hospital; Arthur George Lawrence Reade, Charing Cross Hospital; Hubert George Rickman, St. Mary's Hospital; Stuart MacKenzie Saunders, Science, Art, and Technical School, Plymouth; George Henry Sedgwick and Edward Sutcliffe, Yorkshire College, Leeds; Harold Sigismund Sington and George Theodore Stephens, St. Thomas's Hospital; Harry Ernest Thomas, London Hospital; Samuel Hilton Tinsley, St. Mary's Hospital; Joseph Frederick Trewby, Birkbeck Institute; Frederick Weber and Cyril Oswald Oxford Williams, St. Bartholomew's Hospital; Alfred Gurth Whitaker, Charing Cross Hospital; and William Wynne Williams, King's College, London.

Practical Pharmacy.—John Howard Addinsell, University College, Liverpool, and King's College, London; Edward Guy Anthonisz and Edward Leslie Bartlett, St. Mary's Hospital; Algernon James Beadel, Guy's Hospital; Frank Elliott Bolton, University College, London; John Bryan, London Hospital; Arthur Henley Bloxsome and George Elliott Cathcart, St. Bartholomew's Hospital; Frederick John Cutler, private study; Harold Clapham and Arthur George Cole, St. Mary's Hospital; Robert Harry Lucas Cordner and Edward William Dewey, St. George's Hospital; George De La Cour, University College, London; Reginald Inglis Douglas, St. Bartholomew's Hospital; John Freeman Douse, Guy's Hospital; Bertram Joseph Eccles, Mason University College, Birmingham; Charles Horace Fagan, St. George's Hospital; William James Gifford Gayton and Jonathan Grogono, London Hospital; Robert Gray Gillies, private study; Edward James Gaffney and George Sullivan Clifford Hayes, Guy's Hospital; Frederick Harold Hand, St. George's and St. Mary's Hospitals; William John Hogg, Queen's College, Belfast; Geoffrey Wallace Grainger Hughes, King's College, London; Samuel Clifford Hayman, Herbert James, and William John Jones, University College, Bristol; William Percival Ker, Guy's Hospital; James Malcolm King, Surgeons' Hall, Edinburgh, and University College, London; Francis Courtenay Lambert and Nelson Low, St. Mary's Hospital; Thomas George Miles and Percy Frank Minett, Guy's Hospital; Eric Stewart Marshall and Charles Vere Nicoll, St. Bartholomew's Hospital; Leonard Newsom Morris, University College, Bristol; George Smyth Oades, University College, Bristol, and Charing Cross Hospital; Arthur Carr Osburn, Guy's Hospital; Vining Gedney Joseph Paul and David Phillips, St. Mary's Hospital; Arthur Francis Reardon, St. Thomas's Hospital; Vivian Ernest Ridewood, London Hospital; Ernest Edward Semmence, Surgeons' Hall, Edinburgh, and St. Thomas's Hospital; Arthur Walrond Soper, Guy's Hospital; Harold Foster Strickland, Charing Cross Hospital; Tom Timothy, University College of South Wales, Cardiff; Oswald Henry Vevers, London Hospital; Charles Visger, University College, London; Ernest Walker and Charles Murray Woods, Charing Cross Hospital; John Walker, St. Thomas's Hospital; Theophilus Ralph Waltenberg, Owens College, Manchester; George Hope Warren, King's College, London; Walter John Weston, St. George's Hospital; and Frederick Ernest Wilson, Guy's Hospital and University College, London.

Materia Medica.—John Evans, Cambridge University and St. George's Hospital; Laurence Galsworthy, St. Bartholomew's Hospital; Edward Green, King's College, London; Edwin Walter Routley, Guy's Hospital; and Francis John Russell, London Hospital.

Elementary Biology.—Hugh William Acton, Middlesex Hospital; James Elrick Adler, London Hospital; Arthur Keith Armstrong, St. Bartholomew's Hospital; Edward Leicester Atkinson, St. Thomas's Hospital; Stanley Bott, Wyggeston School, Leicester; Cuthbert Garrard Browne, Westminster Hospital; John Bryan, London Hospital; John Bramley Ball, Laurence Henry Burner, Walter Henry Skardon Burney, Alfred Hollier Clough, and Vincent Ackroyd Palliser Costobadie, Guy's Hospital; Emil Christofferson, University College, Bristol; Vivian Colmer, London Hospital; Charles Arthur Frederick Cresswell, University College, London; Arthur Hubert Davis, St. George's Hospital; George Edward Fritche, Middlesex Hospital; Wilfrid Enos George, London Hospital; Stanley Rider Gibbs, St. Thomas's Hospital; Thomas Reginald Harvey, Guy's Hospital; William John Lennox, Merchant Venturers' Technical College, Bristol; William Sherwood Livock and Arthur Harkness Macdonald, London Hospital; John Eustace Radclyffe McDonagh, St. Bartholomew's Hospital; Arthur Llewelyn Morgan, Frederick Morres, and Henley Hamlyn Moyle, Guy's Hospital; Oswald Sinclair Norton, City of London College; Armstrong Smith, Middlesex Hospital; John Edwin Scales and Lionel Duncan Stamp, Guy's Hospital; John Ronald Rigden Trist, St. Bartholomew's Hospital; Oswald Henry Vevers, London Hospital; Alfred Gurth Whitaker, Charing Cross Hospital; Ernest White, Guy's Hospital; and Everard Lister Wright, St. Bartholomew's Hospital.

THE ST. PANCRAS LUNACY SCANDAL.—It will be remembered that an inquiry was opened by the Local Government Board on July 10th, 1900, concerning certain irregularities which had taken place with regard to the certification and transfer of lunatics. The inquiry was

adjourned on July 12th, but the Local Government Board issued a circular letter which was practically a kind of interim judgment, in which they said that they considered the practice which they knew to exist of relieving officers receiving payments from parish medical officers and proprietors of licensed houses for the reception of lunatics in connexion with the reception of lunatics was indefensible. The Local Government Board have now sent a communication to the St. Pancras Guardians saying that the Local Government Board have decided to allow the incriminated officers to continue in office, but they request that the officers in question may be informed of the Board's grave displeasure at their conduct. Should there be any ground of complaint against them in future with regard to any other matter their present offence will be taken into account. These observations do not apply to Dr. Walter Smith or to Mr. Murphy. The whole case seems to the Board to show the need for increased care in the administration of the Lunacy Acts in certain particulars, and communications are in progress with the Secretary of State and he Lunacy Commissioners upon the subject.

ROYAL ORTHOPÆDIC HOSPITAL.—The annual court of the Royal Orthopædic Hospital, 297, Oxford-street, was held on Feb. 18th in the board-room of the hospital, about 20 governors attending, with Mr. H. H. Marks in the chair. The report of the committee of management was adopted and a resolution was passed confirming a previous resolution giving the committee full power to sell the present site and buy another. Efforts are being made to find a new site in accordance with the recommendation of the Council of the Prince of Wales's Hospital Fund for London. The meeting lasted for two hours and was remarkable for extreme freedom of speech. Considering the heated nature of some of the remarks indulged in by those interested in the welfare of the hospital it is difficult to understand how the deputy chairman, Mr. Ernest Flowers, M.P., could affirm that the work had gone on very smoothly, successfully, and harmoniously.—Mr. H. A. Reeves, one of the surgeons of the hospital, speaking for the surgical staff, roundly declared that if he were chairman he would not sign the report and stigmatised as illegal the resolution giving the committee full power to sell the present site of the hospital valued at £45,000 and to buy another. The paragraph in the report referring to the Prince of Wales's Hospital Fund was, in Mr. Reeves's opinion, simply throwing dust in the eyes of the ignorant public.—Discussing the committee's plans to remove the hospital into the heart of London, Mr G. Barham declared it was one of the maddest schemes in the world, the very maddest he had ever heard.—Dr. D. Walsh said that as it was decided to rebuild the hospital he would like to know if the position of architect to the hospital was to be an honorary post in the future or not.—The Chairman said he did not see how the question arose, but Dr. Walsh insisted on a clear answer to his question. Mr. Flowers said that it was an indecent thing that the point should be called in question by the governors and he resented it most strongly.—Dr. Walsh, however, wanted an assurance in regard to the future architectural charges, whereupon Mr. Flowers said that the architect would never receive a sixpence. He was followed by Mr. Reeves, who said that the question of recompense had cropped up and as the labourer was worthy of his hire it had been considered that if the architect would leave it to the committee he should have an honorarium. The architect at this point entered the room and after the circumstance had been explained to him declared that his post was an honorary one. The proceedings went along fairly quietly for the next few minutes till Mr. Reeves again caused commotion by saying that the committee had made no real effort for the hospital for 25 years. Something, he said, must be done and he proposed raising money for the hospital on the "mutual principle." The explanation of what this meant was difficult to follow, but it somehow led Mr. Reeves to declare that Mr. Marks (the chairman) had said that he would lend £5000 to the hospital, upon which the Chairman remarked that Mr. Reeves's statement was incorrect and his memory defective. It was some time before the meeting got to business again, Mr. Marks saying that he refused to change his chairman's seat into a witness-box for his own cross-examination. Here one of the governors of the hospital said that as the committee had made no effort he thought Mr. Reeves's plan should be considered. The honorary treasurer, Mr. R. B. Martin, M.P., thereupon went into the scheme in detail with Mr. Reeves, but finally the whole matter was ruled out of order by the Chairman. Everything went on again quietly till Mr. Flowers in again discussing the question of removing to another site referred to what he called the painful and contemptible attack on their architect. This naturally brought up Dr. Walsh who vigorously protested against this language and improved the occasion by pointing out that Moorfields Hospital had removed to another site after selling their valuable freehold property with the result that they had plunged themselves into financial ruin.

A PRESCRIBING DRUGGIST.—An inquest was held at Worle, Somerset, on Feb. 11th, upon the body of a man, aged 42 years. The deceased had complained of a sore-throat and consulted a druggist who gave him some medicine. The same night he was seized with a choking sensation in his throat and expired before a medical man arrived. A post-mortem examination showed that death was due to suffocation caused by an abscess discharging into the air-passages.

CARDIFF INFIRMARY.—The management committee of the Cardiff Infirmary has decided that under no circumstances, either of urgency or otherwise, shall surgical instruments belonging to the infirmary be taken away from the institution. This decision has been arrived at in consequence of some members of the staff having borrowed certain instruments and retained them for an unreasonable and unnecessary length of time.

ON the closing of his private military hospital at the Gables, Surbiton, Sir Alfred Cooper has given the bedsteads, bedding, and other requisite articles to St. Thomas's Hospital, as an acknowledgment of the assistance rendered to the sick and wounded soldiers by the medical and surgical staff of that institution.

OVERCROWDING IN KENSINGTON.—This borough council has decided to authorise the medical officer of health to employ *pro tem.* six sanitary inspectors, to inspect the most densely inhabited streets in the borough, and procure the fullest and best information on the question of overcrowding.

BRITISH MEDICAL ASSOCIATION: THE CHELTENHAM MEETING.—A meeting convened by the Mayor was held at Cheltenham a few days ago to take preliminary steps in preparation for the meeting of the British Medical Association in Cheltenham next summer. The Mayor read letters of apology and support from several gentlemen, including Mr. J. T. Agg-Gardner, M.P., who promised a subscription of 10 guineas and asked for approval of the steps which he had already taken in opening a fund for extending hospitality and entertainment to the expected guests.—Dr. Ferguson mentioned that the suggestion that the meeting should be held in Cheltenham had been made from headquarters without solicitation on the part of the district branch. It was 64 years since the association had visited Cheltenham. The members in the Gloucestershire district numbered about 100 and they had already subscribed £500.—Dr. Cardew said, so far as the general programme had been settled, it was as follows—viz., Tuesday, service in St. Matthew's Church, attended by the corporation in state and the members in their robes, followed by the address of the President-elect (Dr. Ferguson) in the Princess Hall, Ladies College; Wednesday, professional discussions; Thursday, further professional work, followed by a public dinner and soirée; Friday, concluding meetings, visit to Gloucester, and other trips; and Saturday, excursions.—Mr. Levy Wood asked whether steps would be taken to bring the Cheltenham waters before the medical profession, and Mr. F. J. Bennett, as a member of the Baths Committee, replied that steps were being taken to have them made up in a palatable aerated form.—The Mayor mentioned that there need be no fear of the town not rising to the occasion. As the time approached it would probably be found difficult to get in the engagements. Colonel Rogers had promised a reception at Battledown Court, a delightful spot for such a gathering, and on Wednesday the day would be given up to civic hospitality. On some other day the Freemasons of Cheltenham and Gloucester would like to offer some hospitality to members of their great brotherhood in the profession.—Dr. E. T. Wilson, in proposing a vote of thanks to the Mayor, expressed the hope that the visit would break down the prejudice which some medical men had against Cheltenham and prove to them that it was not so relaxing as they had supposed.—The meeting then closed.

UNIVERSITY OF CAMBRIDGE.—At the congregation on Feb. 14th the following degrees were conferred:—M.D.: E. S. Verdon, Jesus, and A. J. Collis, Selwyn Hostel. M.B.: F. A. Bainbridge, Trinity. M.B. and B.C.: F. C. Shrubsall, Clare, and A. Emerson, Gonville and Caius.

MR. RALPH STONEY, Colonial Surgeon, has been transferred from the British East Africa Protectorate to the Uganda Protectorate. Having passed the required examination in the Hindustani language he has received the Government grant of £50.

PRESENTATIONS TO MEDICAL MEN.—On Wednesday evening, Feb. 6th, at Wrenbury, Nantwich, a deputation of the members of Court "Wrenbury," No. 769, A.O.F., waited upon Mr. W. Thomson, their late medical officer, and presented him in the name of the Court with a silver salver bearing the following inscription: "Presented to Wm. Thomson, Esq., L.R.C.P. Edin., by the members of Court 'Wrenbury,' 769, A.O.F., in recognition of his services as medical officer during a period of 50 years. Dec. 31st, 1900." Tenure of office during such a lengthened number of years must surely be almost unique in the history of friendly societies, and shows the sympathy existing between the members and their late surgeon.—Mr. Robert Reynolds, M.R.C.S. Eng., of Steeple Bumpstead, Essex, has been the recipient of a testimonial on retiring from his practice—namely, a cheque and an illuminated album. The latter is richly bound and bears the following inscription:—"This album, with 472 names of subscribers appended, together with the sum of fifty-five guineas, was presented to Robert Reynolds, Esq., M.R.C.S., &c., at a public dinner held in the parish of Steeple Bumpstead, Essex, on the 14th day of February, 1901, as a token and expression of the esteem and goodwill for him after 42 years' residence and practice in this parish and neighbourhood by his many friends resident in the following parishes: Steeple Bumpstead, Helions Bumpstead, Birdbrook, Hempstead, Ridgewell, Stambourne, Sturmer, and Cornish Hall End."—At Gunnislake, Cornwall, on Feb. 7th the members of the class of the Callington branch of the St. John Ambulance Association presented Mr. Albert Bowhay, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., D.P.H. Camb., with a dressing-case as a mark of appreciation for his services as lecturer.—The members of the St. Austell (Cornwall) branch of the St. John Ambulance Association on Feb. 11th presented Mr. C. W. Seccombe, L.R.C.P. Lond., M.R.C.S. Eng., with "Osler's Practice of Medicine" as a mark of appreciation for his services as honorary lecturer.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Opening of the Session.

THE King opened in person and with full State ceremonial his first Parliament on Thursday, Feb. 14th. His Majesty, accompanied by Queen Alexandra, drove in state through the streets from Buckingham Palace to the Royal entrance of the House of Lords where he was met by the Chief Ministers of State and various functionaries of the Court. A procession was then formed which marched through the Royal gallery to the throne at the far end of the House of Lords. His Majesty, in presence of Lords and Commons, took the declaration required by the Bill of Rights with regard to the doctrine of transubstantiation and the saying of masses, and having signed the document recited with his own voice the terms of the Royal message to Parliament. Many Members of the House of Lords can only make themselves imperfectly heard owing to the bad acoustic properties of the chamber, but His Majesty, speaking with strong and clear voice and careful emphasis, was clearly heard even at the back of the most distant gallery.

The King's Speech.

There were few points of special interest to the medical profession in the Speech from the Throne. Reference was made to the climatic difficulties met with and overcome by the expedition under Sir James Willcocks in Ashanti and to the suffering and mortality caused by the prolonged drought in India, and nine subjects of prospective legislation were mentioned. Three of these subjects were mentioned without qualification, but the others had attached to them the always-significant observation that they will be dealt with in the course of the session "if the time at your disposal shall prove to be adequate." Among the subjects qualified in this way were the Amendment and Consolidation of the Factory and Workshops Acts, the Better Administration of the Law respecting Lunatics, the Amendment of the Public-Health Acts with regard to Water-supply, and the Prevention of Drunkenness in Licensed Houses and Public Places.

The Midwives Bill.

Early in each session private Members with Bills to introduce engage in a ballot for places for the discussion of these Bills on second reading. The Member who draws the paper marked "No. 1" gets the first choice of place for the measure in which he is interested, he who draws "No. 2" the second, and so on down the list. This ballot took place on Monday, Feb. 18th, and the promoters of the Midwives Bill drew no better figure than "38," this figure being drawn by Mr. Bond, the Member for East Nottingham. On the following day a large number of private Members' Bills were introduced, but the Midwives Bill was not among them.

HOUSE OF COMMONS.

FRIDAY, FEB. 15TH.

Introduction of a Medical Member.

Dr. EDWARD CHARLES THOMPSON, the successor of the late Mr. Macalese in the representation of North Monaghan, was introduced by Captain Donelan and Mr. Patrick O'Brien and took his seat.

Arsenic in Beer.

Mr. CHAPLIN in the course of the debate on the Address raised this question and discussed the action of the Local Government Board in regard to the Manchester epidemic. He argued that the case against arsenic in beer as the cause of this epidemic had been proved and that what was wanted was action rather than further inquiry. There were various methods, he said, by which the matter might be dealt with. The Government might prohibit the use of substitutes altogether, they might limit the prohibition to sugars which had been proved to be injurious, they might restrict the use of these sugars within such limits as would be safe, they might discourage their use by a higher duty on the beer in the production of which sugar was used, or they might charge the duty on the materials instead of on the product. He pronounced no opinion on these proposals. If the Government were not prepared for any of these methods they might by a short Act of Parliament require that when substitutes were used the fact should be declared to the customers. Mr. Chaplin then referred to the communication of Professor Tunnicliffe and Dr. Otto Rosenheim[1] to THE LANCET on the subject of the presence of selenium in brewing sugar and beer. This, he said, was a new terror and it would appear to be quite beyond the scope of the reference to Lord Kelvin's Commission.—Sir CUTHBERT QUILTER spoke in the same sense and made an urgent appeal to the Government to take immediate action.—Mr. WALTER LONG, President of the Local Government Board, defended the action of his department in relation to the Manchester epidemic, and with regard to the general question he insisted that there must be further inquiry. An epidemic of this kind, he said, opened up new fields of inquiry and of knowledge, and this made it his duty to see not only that everything was done that could be done under the law as it stood, not only that all possible information was given to those who were locally responsible for the protection of public health, but also that every inquiry was made that was likely to throw new light on the subject, in order, if necessary, to take any fresh legisiative action that might be taken on the solid basis of ascertained fact. He submitted to the House that, in the present state of their knowledge, there could not be given by those eminent scientific and medical men on whom the Local Government Board relied that clean bill of health which would surely be an absolute condition before it would be possible to exclude everything else and leave the manufacture of beer to one article alone. There was no desire in the appointment of a Royal Commission to delay a proper review of the question. He personally had done his best to get outside advice and opinion as to the course that should be followed, and so far he had not found one eminent scientific man of the opinion that they were wrong in the course they were adopting. With all the goodwill in the world he did not think it would be possible for any man in his position or for any Government to have taken a line other than that which had now been taken.

The South African Hospitals Commission.

Later in the evening three speeches were delivered with regard to the report of the South African Hospitals Commission and the general question of the care and treatment of the sick and wounded during the campaign in South Africa. Mr. BRODRICK, Secretary of State for War, sat in the House at the time, and no doubt he will take an opportunity of replying to the speeches.—Sir WALTER FOSTER repeated his statement that a great deal of the disease that had occurred was preventable. Typhoid fever, he said, must have been foreseen and proper precautions ought to have been taken against it. At the commencement of the war he suggested to the Government that they ought to send out some special corps or body of men to deal with the sanitation of camps and other places where soldiers were congregated, and the War Office having got the opinion of their Director-General decided that these matters might safely be left in the hands of the Army Medical Department. This decision, arrived at on Nov. 9th, 1899, had been absolutely contravened by the report of the Hospitals Commission, where the War Office were recommended to appoint properly qualified officers of the Royal Army Medical Corps to undertake sanitary duties. He therefore wished to know what steps it was proposed to take to carry out this recommendation. With regard to the report generally Sir W. Foster said there was a good deal of whitewashing attempted by the commissioners. The whitewash, however, was not sufficient to extend over the wide surface that had to be covered, and here and there it was so extremely thin that one could see the lurid facts betraying themselves under the coating with which the commissioners had tried to cover them. He believed that the Secretary of State was desirous of meeting the difficulties which had overtaken the Army Medical Service and of making the department better manned and more fit for its duties. This, however, should be done in a spirit of thorough reform. Splendid efforts had been made by private generosity, but he did not think we ought to rely in the future upon

[1] THE LANCET, Feb. 9th, 1901, p. 434.

private generosity in these matters. The taxpayers in this country were willing to find money in millions to make their army efficient and to protect the health of the men and we ought not to rely in the future on private effort coming to our aid. We ought not to rely, either, too much on civil surgeons to supplement the deficiency of the Royal Army Medical Corps, but we ought to equip our army just as thoroughly in the matter of medical service as we ought to do in the matter of artillery. He would, therefore, ask the right hon. gentleman in his reply to give the House some assurance that he would deal with this matter from top to bottom in a thorough spirit.—Mr. W. MURRAY GUTHRIE, the member for Bow and Bromley, who spent many months in South Africa and who gave evidence as to his experiences before the Commission, next addressed the House. He had no doubt, he said, that at first the Government were as ignorant as the country as to the true state of things at Bloemfontein. He remembered the surprise caused at Bloemfontein by the speeches of Sir William Mac Cormac and Mr. Treves in London. The former said that it would not be possible to have anything more complete or better arranged than the medical service in this war. Mr. Treves endorsed those words and went out of his way, if he might say so, to insult a body of women in South Africa, some of whom were perhaps very much in the way in Cape Town, but many of whom were doing service to their country. He did not think their patriotism was any less than that of Mr. Treves. When the celebrated letter of the hon. member for Westminster (Mr. Burdett-Coutts) was published he believed it came like a bombshell to the English people. Then came a debate in the House when the Government promised to appoint a Commission, and he was sorry that they did not consult some of the opposing faction with a view to allowing them to nominate one member to represent their views on the Commission. He was certain that the Government had the intention of getting at the truth of the matter, and he thought that they had made a mistake in not taking that course. If he had had time he would have liked to analyse a good deal of the evidence given before the Commission. He thought he would be able to show that, instead of credence being attached to the evidence given by civilians, more credence was attached to evidence given by the officers of the very branch of the service which was practically on its trial. There was the case of the men at Bloemfontein station. He had been an eye-witness of the events which the hon. Member for Westminster had recorded. In the report of the Commission not only was his story discredited but the story of the very man who was responsible for the mistake occurring was taken for gospel. The Commission also believed Colonel Hexham's story as against that told by the surgeon of the Irish Hospital. The Commissioners in their report stated that the detention of the invalids at the railway station had not occurred often. But one of the witnesses, Captain Lawrence, a railway staff officer, asked whether there were many occasions on which men were kept waiting for a long time at the railway station, replied that he was sorry to say it was of constant occurrence. He suggested that the new committee which would probably be appointed to inquire into the army medical service should not be a departmental committee but a committee of wider scope, having on it some representatives of those civilians who had taken part in hospital work, so that the country should not have to depend entirely for evidence on the Army Medical Service Corps.—Mr. BURDETT-COUTTS, the third speaker, asserted that the inquiry of the Commission had not been conducted in a way calculated to elicit the whole truth and that the defects of the Army Medical Department had been concealed and buried in the lame and impotent conclusions of the report.

MONDAY, FEB. 18TH.

Enteric Fever among the Troops in South Africa.

Mr. BRODRICK, in answer to a question addressed to him by Sir WALTER FOSTER, gave the following approximate figures with regard to enteric fever among the troops in South Africa during the last three months of 1900—viz., October, 568 cases, 98 deaths; November, 1213 cases, 207 deaths; December, 1665 cases, 286 deaths. The total number of cases from the beginning of the war to December, 1900, was 19,101 and of deaths 4233. The number of officers and men invalided for enteric fever who had arrived in England from the beginning of the war to December, 1900, was 10,975.

Lead Poisoning in the Potteries.

Mr. RITCHIE, answering a question on this subject by Sir CHARLES DILKE, said: I am aware that in the months of July, August, October, and December, 1900 (but not in April or in any other month), the reported cases of plumbism in the industry of china and earthenware making were more numerous than in the corresponding months of 1899, the totals being 71 and 50 respectively. But the net result for the year as a whole was a reduction from 249 in 1899 to 200 in 1900, and this has followed upon a previous large reduction between 1898 and 1899. I a few days ago formally proposed a set of new rules to the manufacturers, following in the main the draft issued in August last, but containing certain amendments which appeared to me necessary and reasonable. I might have proposed the rules in this form some time ago, but I have been in negotiation with the representatives of the manufacturers in hope of arriving at a settlement and avoiding arbitration, and I have found them ready to accept with a few slight modifications most of my proposals. On the proposed "standard of insolubility," however, a serious difference of opinion arose between the Government chemist and the manufacturers' expert advisers, and I have come to the conclusion that this difference should be settled by arbitration. There are also certain points on which I am anxious that the workpeople should have an opportunity of stating their views before they are finally settled, and these will be dealt with on the arbitration, at which the workpeople are entitled to be represented.

Proposed State Inebriate Reformatory.

Mr. RITCHIE, in reply to Mr. HOBHOUSE, said that he had received numerous representations from county authorities urging the establishment of a State Inebriate Reformatory. He himself was anxious to see such a reformatory established and he was now in communication with the Treasury on the subject.

TUESDAY, FEB. 19TH.

The Government and the Army Medical Service: Statement by Mr. Brodrick.

Mr. BRODRICK took an opportunity at this sitting during the debate on the Address to reply to the speeches made on Friday with regard to the medical provision in South Africa and the report of Lord Justice Romer's Commission. Great blame, he said, had been thrown on the Army Medical Department and he did not suggest that this department had not many things to answer for, but in considering the mistakes of the department they must bear in mind the part which the House of Commons had had in bringing about the present state of things. Mr. Brodrick recalled that when nearly 14 years ago the late Lord Randolph Churchill carried on his crusade against public expenditure the Army Medical Department was severely criticised. He remembered a strong speech of the Member for Wolverhampton (Sir Henry Fowler) in which he said that there were too many doctors and that the department wanted overhauling, for it cost too large an amount of public money, and the report of the Committee appointed at the time bore out this belief. This Committee, after two years' investigation at the War Office, decided that there were too many doctors and that they were too highly paid, with a too high proportion of retired pay, and that the whole subject required revision. By this the War Office had ever since been influenced. In the House of Commons successive Ministers had laid it down that we must provide for three army corps at home and two abroad, and upon this the arrangements of the Army Medical Department had been made. Could they wonder, then, that when we came to send the equivalent of six army corps to South Africa the medical arrangements should be somewhat strained? Difficulties arose that were not foreseen in sending supplies along lines of communication longer than had ever been necessary in a continental war. The War Department in the matter of medical officers had for the last 14 years been between the upper millstone of a Parliament determined to keep down expenditure and the lower millstone of the medical profession, who denied their best candidates except upon better terms. The War Office did all it could to get better men, but the heads of the profession declared that medical men must have military rank, without which they could not hold up their heads among their military colleagues. He remembered that it was even urged that beyond the titles of "major" and "colonel" the title of "general" should be open to them. Five years ago Lord Lansdowne was assured that unless the title of "general"—not "surgeon-general"—were given other proposals would be useless. But not to trouble the House at length he would sum up what the experience of the war had shown. Mr. Brodrick then said: It has shown, in the first place, that these military titles have not altogether had the best effect. In the second place, the Commission of able, independent men, who whatever we may say of their conclusions certainly held no brief for the Government, have shown in their report that there has been no general disposition on the part of the Army Medical Department to shirk its duties, and that there has been great devotion shown among the medical men. If in some cases there have been defects of organisation and skill, that organisation can be reformed, and want of skill has been due to the fact that officers have been so hardly worked that they have not had proper opportunities of studying their profession. It has been said by the hon. gentleman opposite (Sir W. Foster) that we have not realised the importance of a suggestion that came from himself—that sanitary committees should be sent out to direct sanitary arrangements for the various camps. I think the experience of the war has shown that a committee of that character, or something like it, would have done good service. And, while knowing as I do the devotion to duty of the great mass of medical officers of the Royal Army Medical Corps, I cannot deny that it has been brought out in the course of these inquiries that there was a certain amount of professional jealousy and indisposition to avail themselves of outside assistance in an emergency, and perhaps too much of that red-tape disposition which is supposed to pursue the army in all its courses, which I, at all events, desire to see removed to a great extent. And in this respect let me say that so far from regarding those who have interested themselves in these matters, both here and in South Africa, with any suspicion I thank them for their attempts; I believe that they have been largely productive of good to the public service; and I believe that we may found on the recommendations of the Commission, and on the extraneous assistance we have received, partly from members of this House, a new and satisfactory system, but one which can only be brought about by a drastic reform of the Army Medical Service. But in the emergency as it now exists we cannot pretend to make a complete reform in a few weeks; we are bound to look at this question very carefully, and we are determined to call to our assistance the heads of the medical profession. It may be that by making our terms of enlistment more elastic, it may be that by making them more attractive in other ways, we can obtain a better class of men. All I would say is this, that if the House will give us a little confidence in this matter I will undertake that no effort shall be wanting, that there is no experience we can get but shall be turned to account, and that no past prejudices shall be allowed to intervene or prevent our giving the army in the future an effective medical service.

Dr. FARQUHARSON at a later period of the sitting congratulated Mr. Brodrick on the tone of his speech.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALLAN, FRANCIS J., M.D., D.P.H., F.R.S.E., has been appointed Medical Officer of Health for the City of Westminster.

BERRY, A. E., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health, Burton-upon-Irwell Rural District, vice H. Knowles, deceased.

BLACKETT, EDWARD JOS., M.R.C.S., L.R.C.P., has been appointed Surgeon to the Hospital of St. John and St. Elizabeth, 20, Grove-end-road, St. John's Wood, London, N.W.

BOND, W. A., M.D., D.P.H. Camb., M.R.C.P. Lond., has been re-appointed Medical Officer of Health by the Holborn Borough Council.

BREARS, C. F., M.D., C.M. McGill Univ., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer by the Sunderland Board of Guardians.

BUIST, J. J., M.B. Lond., has been appointed a Police Surgeon for the A, Central Division, Borough of Cardiff.

BULLEID, ARTHUR, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Midsomer Norton (Somerset) Urban District Council, vice A. Hastings Whicher, resigned.

COOMBS, WELLESLEY, F.R.C.S. Edin., has been appointed Honorary Anæsthetist to the Worcester General Infirmary.

FOTHERBY, H. A., L.R.C.P. Lond., M.R.C.S., D.P.H. Cantab., has been appointed Clinical Assistant to the Infirmary, Parish of St. Matthew, Bethnal-green, London.

FRYER, WM. F., L.R.C.P., L.R.C.S. Edin., has been appointed District Medical Officer for the whole Ipswich Union.

GOUGH, H. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Workhouse, Northwich Union, vice T. Moreton, resigned.

JONES, A. L., M.B., C.M. Edin., has been appointed Medical Officer of Health, Oystermouth Urban District, vice J. I. Bevan, deceased.

KELSON, W. H., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the London Throat Hospital.

LALL, C. C., M.B., C.M. Edin., has been appointed Asssistant Resident Medical Officer to the Infirmary, Salford Union, vice C. H. Woodcock, resigned.

LANE, G. J., M.D. Dub., has been appointed District Medical Officer, Bicester Union, vice E. V. Hemingway, resigned.

LOVELESS, W. K., L.R.C.P., L.R.C.S. Edin., has been appointed a District Medical Officer by the Stockbridge Rural District Council.

MCGAVIN, L. H., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Hospital for Women, Soho square, London, W.C.

MACKLIN, THOMAS THORNTON, M.D. Glasg., L.F.P.S. Glasg., D.P.H. Cantab., J.P., has been appointed to the Medical Charge of Troops at St. Mary's, Scilly Islands.

MOORE, THOMAS, M.R.C.S., has been appointed Medical Officer of Health, Hazel Grove and Bramhall Urban District.

NICHOLLS, A. R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Langport Rural District, vice J. Morgan, resigned.

OLIVEY, J. M. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third and Fifth Districts, Poole Union, vice H. W. Scratchley.

PHILLPOT, G. F., L.R.C.P. Edin., M.R.C.S., has been appointed District Medical Officer, Bromsgrove Union, vice J. L. Hobbs, deceased.

PITTARD, M., M.R.C.S., has been appointed a Palice Surgeon for the B, Grangetown, Division, Borough of Cardiff.

TREHARNE, J. L., M.R.C.S., has been appointed a Police Surgeon for the C, Roath, Division, Borough of Cardiff.

URQUHART, A., M.B., Ch.B. Aberd., D.P.H., has been appointed District Medical Officer, Staines Union, vice G. R. Symons, deceased.

WILLAN, L. J., M.R.C.S., has been appointed District Medical Officer, Dorking Union, vice J. D. Rawlings, resigned.

Errata.—In our issues of Feb. 9th and 16th in the "Appointments" column, "Allen, F. J.," should read Allan, F. J., M.D. Edin., D.P.H. Camb., F.R.S.E.; and "Annis, E. G.," should read appointed Medical Officer of Health for the Borough of Greenwich.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BELGRAVE HOSPITAL FOR CHILDREN, Gloucester-street, S.W.—House Surgeon for six months. Gratuity £5, with board and lodging.

BOROUGH HOSPITAL, BIRKENHEAD.—Senior and also Junior Resident House Surgeon. Salary £100 and £80 respectively per annum, with board and washing.

BOROUGH HOSPITAL, Bootle, Liverpool.—Senior Resident. Salary £100 per annum, with board, &c.

CENTRAL LONDON SICK ASYLUM DISTRICT.—First and Assistant Medical Officers and Dispensers. Salary for the First Assistant Medical Officer £100 per annum, and of the Second £75 per annum, each with board and residence.

CHORLTON-UPON-MEDLOCK DISPENSARY.—Resident House Surgeon, unmarried. Salary £130 a year, with furnished rooms and attendance.

CITY OF SHEFFIELD.—Assistant Resident Medical Officer for Infectious Diseases Hospitals. Salary £150 per annum, with board, lodging, and attendance.

COUNTY OF LANARK DISTRICTS OF THE LOWER AND MIDDLE WARDS.—Resident Physician for Lightburn Joint Hospital for Infectious Diseases, Shettleston, near Glasgow. Salary £130 per annum, with board, &c.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Surgeon. Board, residence, &c., and honorarium of £25 after completion of six months' approved service. Also Casualty Medical Officer for six months, renewable. Salary at the rate of £100 per annum.

EYE AND EAR INFIRMARY, Liverpool.—House Surgeon. Salary £80, with residence and maintenance.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, Holborn, E.C.—Honorary Physician Accoucheur.

GENERAL INFIRMARY, Gloucester, and GLOUCESTERSHIRE EYE INSTITUTION.—House Surgeoncy. Salary £100 per annum, with board, residence, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Two House Physicians, unmarried, for six months and nine months respectively. Salary £20, with board and residence in the hospital.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £40, with board and lodging.

ISLANDS OF SANDAY AND NORTH RONALDSHAY.—Resident Medical Officer. Salary £80 per annum, with dwelling-house, offices, garden, and ten acres of ground, subject to annual rent of £22.

KING'S COLLEGE HOSPITAL, Lincoln's Inn-fields, W.C.—Clinical Pathologist.

LIVERPOOL INFIRMARY FOR CHILDREN, Myrtle-street.—House Surgeon. Salary £85 per annum, with board and lodging. Also Assistant House Surgeon for six months. Salary £25, with board and lodging.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £80 per annum, with board, residence, and washing.

LONDON HOSPITAL MEDICAL COLLEGE.—Assistant Demonstrator of Anatomy. Salary £90 a year.

NORTHERN NIGERIA, WEST AFRICA.—Medical Officers, unmarried, aged 25 to 35 preferred. Salary £400 per annum and local allowance of 5*s.* per day during residence.

NORTH RIDING ASYLUM, Clifton, York.—Assistant Medical Officer, not more than 30 years of age. Salary commencing at £125, rising to £175, and £10 in lieu of liquor, with board, lodging, washing, and attendance.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum, all found except board.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100, with board, lodging, and washing. Also Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton.—House Surgeon. Salary £80, with board, lodging, and washing.

ROYAL BOSCOMBE AND WEST HANTS HOSPITAL, Bournemouth.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—House Physician. Salary £50, with board and washing.

ROYAL INFIRMARY, Sheffield.—Junior Assistant House Surgeon. Salary £70 per annum, with board, lodging, and washing.

ROYAL SEA BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

SHEFFIELD ROYAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, lodging, and washing, with an advance of £10 for the second and third years.

SOUTHPORT INFIRMARY.—Resident Senior House Surgeon. Salary £80 per annum, all found.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at the rate of £24 per annum, with board, washing, and residence.

STOKE-UPON-TRENT UNION.—Medical Officer. Salary £200 per annum, with board, washing, and furnished apartments at the hospital.

ST. BARTHOLOMEW'S HOSPITAL.—Ophthalmic Surgeon.

ST. MARY'S HOSPITAL, Paddington, W.—Casualty Physician. Salary £75.

SUFFOLK GENERAL HOSPITAL.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

TOWNSHIP OF TOXTETH PARK, Liverpool.—Assistant Medical Officer of the Workhouse and Infirmary. Salary £100 per annum, with board, washing, and apartments.

URBAN DISTRICT COUNCIL OF BARNES.—Medical Officer of Health and Superintendent of Isolation Hospital. Salary £150 per annum.

WARNEFORD HOSPITAL, Leamington.—House Surgeon. Salary £100 per annum, with board, washing, and apartments.

WARNEFORD ASYLUM, Oxford.—Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodgings, washing, and attendance.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and House Surgeon for six months. Board and lodging provided.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Physician for six months. Honorarium at the rate of £75 per annum and board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BOOBBYER.—On Feb. 19th, at 56, Burns-street, Nottingham, the wife of Philip Boobbyer,, M.B., of a son.

EVELYN.—On Feb. 11th, at Micklegate, York, the wife of William A. Evelyn, M.D., of a son.

FARNFIELD.—On Feb. 14th, at Mere, Wilts, the wife of William Walter Farnfield, M.R.C.S., L.R.C.P. Lond., of a daughter.

LOWE.—On Feb. 15th, at Horninglow-street, Burton-on-Trent, the wife of Walter G. Lowe, M.D., of a daughter.

LUFF.—On Feb. 17th, at 31, Weymouth-street, W., the wife of Arthur P. Luff, M.D., F.R.C.P., of a son.

MURRELL.—On Feb. 14th, at Blenheim Lodge, London-road, Reading, the wife of G. F. Murrell, M.B. Lond., of a daughter.

MARRIAGES.

LACKIE—EVANS.—At Felinfoel parish church, on Feb. 14th, by the Rev. J. W. Roberts, M.A., assisted by the Rev. David Davies, M.A., vicar of Llangennech, James Lamond Lackie, M.D., F.R.C.P.E., to Elizabeth Hilda, youngest daughter of David Evans, D.L., of Llangennech Park, Carmarthenshire. At home, 1, Randolph-crescent, Edinburgh, March 13th and 14th.

WINDLE—NAZER.—On Feb. 14th, at the Church of S. Catherine of Siena, Birmingham, Bertram C. A. Windle, M.D. D.Sc., F.R.S., Professor of Anatomy in the University of Birmingham, to Edith Mary, daughter of O. Nazer of Ashford.

DEATHS.

COOK.—On Feb. 16th, after three days' illness, Mabel Cook, the esteemed and valued matron of the British Lying-in Hospital, Endell-street, London, W.C., aged 31 years.

WEBSTER.—On Feb. 16th, suddenly, at his residence, Duppas-hill, Croydon, Geo. Leonard Webster, M.R.C.S., aged 40 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A QUACK AT PONTEFRACT: WISE WORDS FROM A CORONER.

AN inquest was recently held at Pontefract to inquire into the circumstances attending the death of a young woman named Elizabeth Prince, aged 19 years, who had up to a few days previous to her death enjoyed good health and followed her usual employment at certain liquorice works. When the girl was taken ill a herbalist named Tempest was called in, who treated her for "head complaint." The mother told the coroner that she thought Tempest was a fully qualified man or she would not have had him but would have called the medical officer of the club. A neighbour had told her that Tempest had said that he could give a death certificate if required. She asked for a death certificate when her daughter died, and Tempest said that he would send it, but witness heard no more until the police called. Tempest was at her house twice on the day that the deceased died, and though he was there at 2.30, and she died at four o'clock, he did not say that she was worse or that she was likely to die.—The registrar of births and deaths said that, acting upon instructions previously received from the coroner, he had refused to accept Tempest's certificate of death and had acquainted the coroner with the facts of the case.—The medical man who made a post-mortem examination of the body said that everything was normal except the left lung. Death was due to inflammation of that lung. There was nothing at all to indicate that there had been any "head complaint."—In answer to the foreman witness said that life was so uncertain that he could not definitely say that the girl would have recovered if she had been attended by a qualified medical practitioner: she would certainly have had a better chance. He considered it dangerous to the public welfare that these so-called doctors should be in practice. In summing up the coroner (Mr. Maitland) said that whenever he came across a case in which these quacks were concerned he would inquire carefully into it and if necessary go to the furthest extreme. He had already had one inquiry where Tempest had given a certificate of death, but here he seemed to have been on the wrong tack altogether, treating the deceased for "head complaint," whereas it had been proved that her head was all right and that she had died from inflammation of the lung. Had a proper medical man been called in in the first instance it was probable that the girl would have been still alive. Tempest had clearly held himself out as duly qualified, for they had it in evidence that he had told a Mrs. Boothman that he was so and that if required he could give a death certificate. It certainly seemed to him that the matter had reached a stage when the General Medical Council might take the case up again as they had done once previously. He did not think that these quacks should be allowed to go up and down the country and he thought that their employment was only due to ignorance. The jury returned a verdict that the woman had died from inflammation of the left lung, the foreman adding that the jury wished to condemn those of the public who engaged such unqualified quacks.

THE REMOVAL OF DEEP SUTURES.

To the Editors of THE LANCET.

SIRS,—All surgeons and nearly all general practitioners are well aware that the removal of deep sutures causes a considerable amount of pain to the patient and calls for the exercise of an appreciable amount of force on the part of the operator. Especially is this the case after operations for the repair of a ruptured perineum, or after immediate suture of deep lacerations of that structure. All trouble of this kind can be avoided by the very simple plan of cutting the stitches on one day and withdrawing them the next. Anyone doing this for the first time will be surprised to find how easily and painlessly they come out, and the reason for this will be apparent on a moment's consideration.

I am, Sirs, yours faithfully,

Wylam-on-Tyne, Feb. 18th, 1901. W. H. BISHOP.

*** The method advocated by our correspondent is fairly well known, but its value is worthy of a wider recognition, as it does much to relieve patients who often appear to dread the removal of stitches more than they dreaded the operation itself.—ED. L.

THE DISCRETION OF A CORONER.

To the Editors of THE LANCET.

SIRS,—Will you kindly give me your opinion on the following facts. A child, 18 months old, whom I have never seen before, was brought to my surgery one evening about 8.30 P.M. in a moribund condition, deeply cyanotic, with abdominal breathing. I found on inquiry that the child had been ill a fortnight but had no medical attendance whatever. On examination there was complete dulness on the right side as far as the clavicle. I diagnosed an empyema and told the mother that the child had not long to live. It died at 11 P.M. the same evening. I refused a certificate. The facts were laid before the coroner and he refused to hold an inquest. Kindly say (1) if you consider I was not justified in refusing a certificate, which I did on the grounds that I had not attended the deceased in its last illness, and that I was not aware of the cause of the empyema, both of which facts I should have had to certify, and (2) has the coroner arbitrary power of this nature to override a medical opinion and take the case right out of a medical man's hands?

I am, Sirs, yours faithfully,

Feb. 17th, 1901. J. M.

*** A coroner decides, as the result of preliminary inquiry, whether it is necessary to hold an inquest into the cause of a death. If he is satisfied that a death is natural he need not hold the inquest. He is not bound to be clear about the pathology of the case. In the circumstances narrated by our correspondent we are surprised that no inquest was held.—ED. L.

"THE CASE OF MR. JOSEPH HENDERSON MARTIN."

To the Editors of THE LANCET.

SIRS,—Since my letter in THE LANCET of Feb. 9th, p. 443, I have received the additional subscriptions which I here acknowledge, and these have been forwarded to Mrs. Martin. Her gratitude for this timely help from known and unknown friends is unbounded. Only those who have found themselves absolutely destitute and with five young children dependent on them, and who have then received assistance from totally unexpected sources, can realise the feeling of thankfulness and encouragement which these generous gifts have brought to this poor lady in her affliction.

I am, Sirs, yours faithfully,

Chester-le-street, Feb. 19th, 1901. H. LYON SMITH.

"A MISTAKE SOMEWHERE."

To the Editors of THE LANCET.

SIRS,—Your correspondent "H. W.," in THE LANCET of Feb. 16th, p. 524, under the heading "A Mistake Somewhere," assumes that there must have been an error in reporting Lord Lister to have stated that the inmates of a particular lying-in institution were better off than women attended by general practitioners "who hitherto had not been persuaded of the importance of antiseptic precautions." There is no error, alas! at any rate in regard to the fact conveyed by this statement. Attention has on more than one occasion been called to the fact that while in maternity hospitals the puerperal mortality has been reduced almost to vanishing point by the methodical use of perchloride of mercury that in general practice has remained practically what it was before the introduction of this beneficent application of antiseptic methods. Although the relatively high mortality of private patients

cannot fairly be laid exclusively at the door of the attendant physician it is hardly open to question that much of it is due to the systematic neglect of the simplest precautions, as many of us can testify from personal experience. The matter is one which deserves to be brought prominently before the profession, since it is one which seriously reflects on the manner in which midwifery cases among the poorer classes are attended. I am, Sirs, yours faithfully,

ALFRED S. GUBB, M.D. Paris, &c.

Gower-street, W.C., Feb. 9th, 1901.

A REALLY CLEVER DOCTOR.

THE following advertisement appeared in a recent issue of the *Morning Post*:—

CAN any Lady RECOMMEND a really Clever DOCTOR, for a Confinement, whose fees are not high, in Chelsea or the immediate neighbourhood?—Address, Doctor, 1594, "Morning Post" Office Strand W.C.

The lady who requires a "really clever doctor" to attend her in her confinement must be under the impression that "real cleverness" in a medical man is as easily detected by the lady who is attended by him as the "real goodness" of a "really good cook" is appreciated by her mistress. She has followed the form which she has been accustomed to use in advertising for her servants so closely, including the proviso as to fees as a substitute for "state wages required," that we wonder she did not add "personal character indispensable" or specify the views as to alcohol and religion which she would prefer in her medical attendant. The answers received should be interesting, but we hope the advertisement will not become a precedent for others.

"MEDICAL SUPERSTITIONS."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "M.B. Lond.," in THE LANCET of Feb. 16th, 1901, p. 524, who is preparing a lecture on Medical Superstitions, should consult: (1) "Folk Medicine," by Black, published by the Folk Lore Society; (2) "Leechdom's Wortcunning and Starcraft," by the Rev. Oswald Cockayne, three vols., published under the direction of the Master of the Rolls; (3) Pettigrew, "Superstitions Connected with the Practise of Medicine"; (4) Lady Wilde, "Ancient Cures, Charms, and Usages in Ireland"; (5) Folkard, "Plant Lore Legends and Lyrics"; and (6) Leland, "Gypsy Sorcery."

I am, Sirs, yours faithfully,

Paris, Feb. 19th, 1901. OSCAR JENNINGS.

To the Editors of THE LANCET.

SIRS,—Your correspondent "M.B. Lond.," in THE LANCET of Feb. 16th, p. 524, will find a very interesting, copious, and full account of medical superstitions in different countries in bygone days in "The Origin and Growth of the Healing Art," by Edward Berdoe, 1893, published by Swan Sonnenschein and Co. J. Cordy Jeaffreson, whose death at the age of 70 years was announced in the papers a few days ago, wrote "A Book about Doctors," two vols., published by Hurst and Blackett, which deals briefly with superstition in connexion with the healing art. The *Hull Press* issued "The Doctor in Medicine, Folklore, &c.," by William Andrews, in 1896.

I am, Sirs, yours faithfully,

Wivenhoe, Feb. 16th, 1901. WILLIAM H. HEWLETT, M.D.

AN AWKWARD PREDICAMENT.

THE February number of the *Maryland Medical Journal* states that Dr. W. E. Grimm of Patterson Creek, Western Virginia, was arrested in Cumberland on Jan. 3rd and held under bail to await the action of the grand jury upon a charge of practising medicine in Maryland where he is not legally qualified as a practitioner. Dr. Grimm's offence consisted in crossing the boundary line for a distance of some 400 yards to attend the negro labourers quarantined with small-pox at Pinto, Allegany county.

Councillor.—We are of opinion that it is not advisable, or for the public advantage, that the appointments of medical officer of health and public analyst in large districts such as the metropolitan boroughs should be combined in the same person. The science and practice of sanitation are in themselves sufficient to occupy all the time of a medical officer who discharges his duties efficiently, in which case he would be prevented from giving that systematic attention to laboratory work which is essential to the performance of the duties of a public analyst. There are competent officers, we know, who combine both posts, but the combination is nevertheless inadvisable.

Worried.—It is not obligatory upon B to tell C. In our view he has discretion because the receipt of the confidence was not sought by him. He should be guided solely by consideration of what is best for C and D. If the message from the dead can do them no good, can be no solace to them, and may cause pain to either or both of them, our advice to B is that he should remain silent.

M.—Such wholesale dissemination of testimonials may lay our correspondent open to criticism. Copies should be marked "private," and great care should be taken to send them only to members.

C. M. C. (Berkswell).—We recommend that the patient should consult a medical man. If he considers a second opinion necessary he will advise her whom she should consult.

W. T.—Massage is taught at some hospitals as part of the routine training of the nurses, but we do not know which is the best place for the purpose.

Medical Student.—A medical student cannot act as a public vaccinator.

R. C. G.—We do not give medical advice.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (27th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (2nd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.) St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (25th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—6.30 P.M. Council Meeting. 8 P.M. Casual Communications:—Mr. W. Hern: Some Early Human Skulls.—Mr. H. Ll. Williams: Two Cases of Absorption of Roots. Paper:—Mr. W. L. H. Duckworth: Dental Fragments, probably of the Third Premolars, found in certain Jaws of Man and Animals (illustrated with lantern slides). Adjouned discussion on Mr. T. E. Constant's paper on the Etiology of Superior Protrusion.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. A. Doran: Painless Calculous Pyonephrosis without Fear, Nephrectomy, Recovery.—Dr. A. Lewers: On Fibroids largely involving the Cervix Uteri, with notes of cases.

TUESDAY (26th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Sir Dyce Duckworth and Dr. A. E. Garrod: A Contribution to the Study of Intestinal Sand with notes on a Case in which it was passed.—Mr. A. E. Barker: On Cases Bearing upon the Question of the Limitation of Enterectomy.

WEDNESDAY (27th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8 P.M. Council Meeting. 8.30 P.M. Sir Mitchell Banks: The Neglect of the Actual Cautery in Surgery and its Value in the Treatment of Pruritus Ani. (Second Hunterian Lecture.)

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Meeting. (The meeting which should have been held on Jan 23rd was, by a unanimous vote of the Council, adjourned as a mark of respect for the memory of her Most Gracious Majesty, Queen Victoria.)

FRIDAY (1st).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith-road, W.).—Clinical Evening.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8 P.M. Special General Meeting to consider the proposed new rule and amendments thereto. 8.45 P.M. Exhibition of Living Cases, Specimens, &c., by Mr. C. Williams, Dr. Walls, Dr. J. Donelan, Dr. Toogood, Dr. Dockrell, and Dr. Henry.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (25th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Dr. T. G. Brodie: The Vascular and Muscular Mechanisms of the Lung, and the Action of Drugs upon this Organ. (Arris and Gale Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Galloway: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Beddard: Some Points in the Use of Opium.

TUESDAY (26th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. S. J. Sharley: Consultation. (Medical).

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Dr. A. Macfadyen: The Cell as the Unit of Life.

WEDNESDAY (27th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Dr. T. G. Brodie: The Vascular and Muscular Mechanisms of the Lung and the Action of Drugs upon this Organ. (Arris and Gale Lecture.)

LONDON THROAT HOSPITAL (204, Gt. Portland street, W.).—5 P.M. Dr. Stoker: Chronic Glandular Disease of the Nose and Nasopharynx. (Post graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—2–3.30 P.M. Mr. H. Finch: Class. Clinical Microscopy. 4 P.M. Mr. P. J. Freyer: Consultation. (Surgical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Kidd: Laryngeal Tuberculosis.

THURSDAY (28th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. J. F. J. Sykes: The Influence of the Dwelling upon Health. (Milroy Lecture.)

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Dr. W. Wingrave: The Nature of Discharges and Douches, with especial reference to Respiratory and Auditory Tracts.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration:—Dr. P. S. Abraham.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Beddard: Angina Pectoris.

CHARING CROSS HOSPITAL.—4 P.M. Mr. Wallis: Surgical Cases. (Post-graduate Course.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration.

FRIDAY (1st).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Dr. T. G. Brodie: The Vascular and Muscular Mechanisms of the Lung and the Action of Drugs upon this Organ. (Arris and Gale Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Gunn: Consultation. (Eye.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. P. Parkinson: Clinical and Pathological Demonstration.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, **AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.**

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES. 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

ON

PUBLIC HEALTH AND HOUSING:

THE INFLUENCE OF THE DWELLING UPON HEALTH IN RELATION TO THE CHANGING STYLE OF HABITATION.

Delivered before the Royal College of Physicians of London,

BY JOHN F. J. SYKES, M.D., D.Sc. EDIN.,

MEDICAL OFFICER OF HEALTH, ST. PANCRAS; LECTURER ON PUBLIC HEALTH, GUY'S HOSPITAL.

LECTURE I.[1]

Delivered on Feb. 28th, 1901.

INTRODUCTORY.

MR. PRESIDENT AND GENTLEMEN,—The subject I propose to submit to your attention presented some difficulty in framing a short title. My object is to consider the influence of the dwelling upon health in relation to the rapidly changing style of habitation, and might perhaps briefly be described as "public health and housing." It is patent to all, especially in the metropolis, that the growth and pressure of population is altering the mode of living and the exclusiveness of the house of former days is giving way to a closer association of habitations. Amongst the affluent and middle classes mansions are now often shared by families; flats, with and without commissariat departments, are springing up on all sides; boarding-houses and residential clubs are increasing in number; and hotel life has become fashionable. Amongst the working and poorer classes existing houses are being more and more sub-divided into tenements, flats of a small kind are erected in increasing numbers, poor men's hotels or cubicle lodging-houses are introduced and family lodging-houses or boarding-houses for the poor are coming upon the scene. The new conditions to which dwelling-houses are now being subjected are becoming increasingly important; more especially does this apply to the dwellings of the working and poorer classes.

The overpowering predominance of the housing question upon the health and vigour of the people is reflected in the fact that in London alone, at the census of 1891, of a population of four and a quarter millions, no less than two and a third millions, over one-half of the community, lived in small dwellings of from one to four rooms. The public health is influenced, not only by the overcrowding and misusage of houses, but also by the construction and arrangement of dwellings, and both are equally important.

It is remarkable that the most serious public health problem now confronting us at the end of the Victorian reign, the most prosperous period of English history, was also the most serious public health problem met with towards the end of the Elizabethan reign 300 years earlier and the next most prosperous period of our history. In each period the cause and effect have been the same. Increased prosperity acts as a stimulus to the growth of towns to such a degree that the crowding of population into cubic space and of houses upon square space becomes a danger to the public health and well-being of the community. In the Acts of the Privy Council, printed and published a year ago, will be found [2] a series of letters addressed in 1590 to the Lord Mayor of London, the Master of the Rolls, and others, commanding them to enforce the Royal proclamation of 1580 and a subsequent statute against the excess of new buildings being erected, the sub-dividing of habitations into several dwellings, and the taking in of inmates "whereby groweth infections of deadly sickness," and "the pestering of many families in one small house," and the "City hath been largely increased to the decrease of other towns, boroughs, and villages within the realm." By statute in 1593 it was provided that no new buildings, except for the better classes, were to be erected within three miles of London and Westminster, and no existing buildings were to be sub-divided, and in 1602 by proclamation newly-built houses were ordered to be demolished. But Stow tells us that little was done and small effect followed. In fact, the disease had not been diagnosed and the proper remedies had not been applied.

It is now no longer resented that the growth of a city should proceed by the influx of population from the country towards the centre, and it is now recognised that the expansion of commercial and professional activity in the city is ever driving the resident population away from the centre towards the periphery,[3] tending to cause closer and closer compression of the people, enhancing the value of the land, increasing the difficulty of the bulk of the population to find room, raising the rental of houses, and reducing the provision of accommodation and accessories in dwellings, and all that this connotes, to the smallest proportions. This is the malady; the remedies prescribed have been numerous and many interests have to be reconciled. I propose to regard the malady and the remedies from the point of view of health and the bodily vigour necessary to carry on the life of our working population.

We are becoming more and more town-bred, and the stamina, energy, and health of the population must be maintained. From time to time it has been said that the housing question is a simple one and that the remedy merely requires that the necessary dwelling accommodation should be defined and enforced. Those familiar with the subject recognise that this is begging the whole question, as the dwelling accommodation necessary is the very thing that all deep thinkers and earnest investigators have been endeavouring to find, and the more they inquire into and work upon the subject the more complex they find are the requirements and the more numerous the points of view from which they have to be regarded—health, construction, economics, and so many other factors governing the question.

Statute already provides that every person in a workshop or factory is entitled to 250 cubic feet of air space and 400 cubic feet during overtime. Although there is no similar statutory definition of overcrowding applicable to dwellings by-laws provide for at least 300 cubic feet of space per head in common lodging-houses and 300 or 400 cubic feet in houses let in lodgings or tenement houses when registered. These by-laws also provide for one w.c. for every 12 persons (in London this is statutory for all houses), the use of a refuse receptacle, of water, and of drainage. Further, there are by-laws and regulations as to drainage, water-supply, and buildings.

Without accepting these provisions as ideal it is evident that legislation has provided some kind of minimum. It is the altered conditions of present-day life that require to be reconsidered and the standards correspondingly altered so as to rest upon a basis more in consonance with physiological requirements rather than the mere packing together of human beings.

Previously to and during the major part of the Victorian period each dwelling-house was constructed to suit the needs of a particular class of family—the one- or two storied cottage for the poorer classes, the six-, eight-, or 10-roomed house for the middle classes, and mansions for the wealthy. The increased prosperity and the increased flow of population into towns during the latter Victorian period led to such a concentration of population that under the increased pressure cottages and smaller houses became insanitary areas, are fast disappearing, and are being reconstructed in flats; terrace houses are being more and more subdivided and sublet in smaller dwellings; and the largest houses and mansions are being altered in construction or reconstructed for other usage.

In the new century London especially will continue to respond still more rapidly to the pressure and will undoubtedly become largely a city of houses in flats or floors of separate dwellings. It is well for public health to recognise this betimes and to ascertain the conditions that will make for deterioration of health in order that they may be avoided both in construction and usage. If the poorer classes are housed in such a manner as to deteriorate health other classes must also suffer, both directly and indirectly, so that the mode and effects of housing become matters of vital interest to all classes. The medical profession appreciate this probably more than any other body of the community.

My matter divides itself naturally into three portions

[1] Lectures II. and III. will be delivered on March 5th and 7th, 1901, respectively.

[2] Acts of the Privy Council (printed edition), vol. xix., pp. 188, 278, 324, 348. See extracts appended hereto.

(1) the ascertained effects upon health of certain conditions of habitation; (2) construction and misconstruction; and (3) usage and misusage; and under these heads I propose to deal with the subject.

I.—THE ASCERTAINED EFFECTS UPON HEALTH OF CERTAIN CONDITIONS OF HABITATION.

The Effects of Density of Population.

Density of population is usually stated as density upon area, per square mile or per acre, or as density in cubic space per house or per room. The square measures are definite, but the cubic measures vary, within limits, according to the size of the houses or rooms. It may be assumed that beyond a certain point increasing density of population upon area, in the absence of hygienic measures, would result in increasing mortality, and that in proportion to the application of these measures the mortality would diminish. If the population were distributed equally upon the land measurement over large areas would be more reliable, but when it is mainly aggregated in large towns this measurement gives the mean of urban and rural conditions.

Density upon Square Space.

Density per square kilometre.—As illustrative of this demographic method of stating the effects of density upon nations the following figures may be quoted:—

TABLE I.—*Density of Population and Mortality in 1886.*[4]

Countries.	Inhabitants per square kilometre.	Births per 1000 inhabitants.	Deaths per 1000 inhabitants.
Norway	6	30·9	16·1
Sweden	11	29·8	16·6
Denmark	15	30·9	16·1
France	72	23·9	22·5
Germany	86	37·1	26·2
Italy	105	36·4	28·3
England and Wales (1886)	182	32·8	19·5
Lancashire (1886)	247	33·7	21·9

Density per square mile.—The late Dr. Farr[5] estimated that the mortality of districts was nearly as the sixth root of the density of the inhabitants—subsequently amended to slightly over the eighth root—and he framed this table to illustrate his later formula:—

TABLE II.—*Annual Rate of Mortality per 1000 for the 10 years 1861–70 in Seven Groups of Districts of England and Wales (exclusive of London) and the Mortality deduced from the Densities of Population in those Groups.*

Number of group.	Number of districts in each group.	Range of mortality.	Density. Persons to a square mile.	Observed mortality.	Calculated mortality.
England and Wales (exclusive of London) ...	593	15–39	315	22·00	20·41
I.	53	15–17	166	16·75	18·90
II.	345	18–20	186	19·16	19·16
III.	137	21–23	379	21·88	20·87
IV.	47	24–26	1718	24·90	25·02
V.	9	27–30	4499	28·08	28·08
VI.	(Manchester.)	32	12,357	32·49	37·70
VII.	(Liverpool.)	39	68,823	38·62	36·74

That death-rates are not determined simply by density of population over large areas was shown by Dr. Ogle[6] in a table relating to the decennium 1871–80, part of which is reproduced below, and in which it was also shown that any regular progressive effect of density upon mortality did not become uniform until the population approached accumulation, so as to be measurable by persons per acre rather than per square mile.

Pursuing the same subject, Dr. Tatham[7] in tables relating to the decennium 1881–90, part of which is also reproduced below, has shown that the relationship of density and mortality is too complex to admit of being expressed by a formula, such as Dr. Farr's, that when death-rates corrected for age and sex distribution are used the mortality appears to increase in more regular progression with increase of density, and that improved sanitation has lowered the ratio of mortality to density.

TABLE III.

1871–80			1881–90	
Persons per square mile.	Crude annual death-rate.	Acres to a person.	Persons per square mile.	Corrected annual death-rate.
194	18·53	3·30	139	12·70
200	15·60	3·20	149	13·45
211	17·58	3 04	187	14 48
217	19·48	2·94	214	15·41
253	14·48	2·53	307	16·47
258	16·63	2·48	435	17·35
458	20·56	1·40	662	18·55
677	21·54	0 95	1281	19·39
1301	22·55	0 49	1603	20·43
1819	23·54	0·35	2437	21 47
2166	24 41	0·30	3299	22·50
2819	25·54	0·23	5329	23·41
2944	26·26	0·22	4295	24·51
6144	30·23	0·10	5722	26·22
—	—	—	19584	33·00

It is obvious from the above table and the preceding that any formula would require an alteration and progressive increase in the root of the density to measure the mortality and keep pace with the progress of sanitation from decennium to decennium. Compare the following figures of density and mortality in the three preceding tables: 1718, 24 9; 1819, 23·5; and 1803, 26·4. The tables not only show in relation to density a progressive decrease of mortality both in the more and the less populated districts, but also that in the more populated districts or towns the decrease is relatively greater than in the country. Compare also the table in the Registrar-General's annual reports of the mortality in town and country districts through a long series of years. This may be attributed to improved domestic and municipal sanitation, but factory legislation has also contributed its quota, occupation being an important factor in the mortality of adults, and especially male adults.

In the Decennial Supplement to the Fifty-fifth Annual Report of the Registrar-General for the years 1881–90 Dr. Tatham compared the mortality of occupied males over 15 years of age in London, in industrial districts, and in agricultural districts, embracing more than half the occupied males in England and Wales in these three sections, and he showed in the following table that each age-group the highest death-rate occurs in the industrial and the lowest in the agricultural districts, London occupying an intermediate position:—

TABLE IV.

—	15	20	25	35	45	55	65 and upwards.
All occupied males	100	100	100	100	100	100	100
Occupied males (London)	108	100	112	125	123	120	108
Occupied males, industrial districts	120	109	119	128	135	137	118
Occupied males, agricultural districts	82	92	82	72	67	71	92

[4] The foreign density figures are taken from the article upon demography by M. Jacques Bertillon in the Encyclopédie d'Hygiène of Dr. Jules Rochard, vol. i., p. 129; the birth- and death-rates and also the English densities from the Annual Report of the Registrar-General.

[5] Supplements to the fifth (1843) and to the thirty-fifth (1873) Annual Reports of the Registrar-General.

[6] Supplement to Forty-fifth (1885) Annual Report of the Registrar-General.

[7] Supplement to Fifty-fifth (1895) Annual Report of the Registrar-General.

Of course, in spite of improved conditions of sanitation and occupation, there will always remain the difference between the air of the country and the town.

It may be concluded that the statistics extending over large areas and calculated per square mile do not form any standard of the health of individual districts or parts of districts subject to very variable amounts of provision for sanitary requirements, especially land drainage, sewerage, and water-supply, and consisting of populations also varying considerably in age, sex, and occupation. With regard to density over smaller areas, as the populations, whether of rural or of urban districts, are mainly aggregated in villages, towns, and cities, it follows that better results are obtained by comparing the statistics of these conglomerations. But even towns differ so greatly in the amount of open spaces and vacant land that the density ratio is not generally a reliable measure of comparison, even when the conditions of water-supply, sewerage, and refuse removal are similar. It is in constant record that urban mortality is highest in districts towards the centre of a city and lower towards the periphery, is most marked in children under five years, and in diseases affecting the respiratory organs. London furnishes ample statistics establishing this in the Registrar-General's returns. The results of medical observations have also placed on record the effects of towns in lowering vitality and energy, enfeebling health, impairing nutrition, and diminishing resistance to disease.

Density per acre.—When particular areas of towns are taken the figures become of greater utility and for the purpose of showing and comparing the effects of density combined with similar insanitary conditions the principal statistical facts with regard to the Boundary-street area, Bethnal Green,[8] and the Churchway area, Somers Town, St. Pancras, are compared in the following table with London as a whole:—

TABLE V.

—	Boundary-street area.			London.	Churchway area.			
	Period.	Boundary-street area.	St. Matthew, Bethnal Green.		Period.	Churchway area.	Somers Town.	St. Pancras.
Area in acres...	1889-90	15	755	77410	1888-90	1½	181	2672
Density per acre	,,	373	168	58	,,	446	183	88
Birth-rate per 1000 population	1887-90	44·6	37·8	30·3	,,	26·8	33·9	30·1
Death-rate under one year per 1000 births	,,	252	159	151	,,	393	172	153
Total death-rate per 1000 population...	1888-90	39·3	22·5	18·9	,,	37·4	23·1	19·1
*Zymotic death-rate ...	,,	9·8	3·8	2·6	,,	5·0	3·2	2·5
†Tubercular death-rate ...	,,	4·4	2·7	2·7	,,	6·7	3·6	2·8
‡Respiratory death-rate ...	,,	12·0	5·6	4·0	,,	11·7	5·5	4·1

* *Zymotic diseases.*—Small-pox, measles, scarlet fever, diphtheria, whooping-cough, typhus, enteric, and continued fevers, diarrhœa, and cholera.

† *Tubercular diseases.*—Phthisis, tubercular meningitis, tabes mesenterica, rickets, scrofula, and other forms of tuberculosis.

‡ *Respiratory diseases.*—Bronchitis, pneumonia, pleurisy, asthma, lung disease, laryngitis, and non-membranous croup.

An unhealthy or insanitary area embraces certain main objects of consideration—the site, the relationship of the houses to each other, the houses themselves, and the class of inmates. Mere density alone of square space is insufficient to produce all the results seen in the preceding table, as shown by the dense population housed on the areas of some prisons, reformatories, and other public institutions. The same applies to large blocks of artisans' dwellings, which will be considered later; in these the relationships of the houses to each other is immensely improved, and the inmates are a picked class.

These comparative figures show that with the increasing density on square space there is an increasing general and special mortality in insanitary areas. The general mortality increases at all ages but particularly under one year. The special mortality shows the greatest increase amongst infectious diseases, the next greatest amongst tuberculous diseases, and the next amongst respiratory diseases. If all infectious cases be promptly removed to hospital and disinfection and cleanliness be enforced the increases tend to take place in the reverse order, the respiratory diseases first, and the infectious diseases third, the tuberculous still remaining second, being largely influenced by pulmonary tuberculosis. This is exactly what *a priori* might be expected, increased density in the same average size of house, lower vitality of the occupants, enhanced predisposition to diseases produced or conveyed aerially. In reference to this aerial influence Dr. Ogle pointed out[9] that if a series of industries be arranged in the order of the purity of the air breathed, apart from dusty occupations, the order will also be that of the mortality from diseases of the respiratory organs together with phthisis.

TABLE VI.—*Comparative Mortality of Males over 15 Years of Age Working in Air of Different Degrees of Purity from Diseases of the Respiratory Organs and Phthisis, the Mortality of all Males over 15 Years being taken as 1000.*

Industries.	Diseases of respiratory organs.	Phthisis.	Total.
Fishermen	90	108	198
Agriculturists...	122	115	237
Grocers	116	167	283
Drapers	129	301	430
Tailors	186	285	471
Printers	116	461	627

These results show the effects of fresh and foul air.

Compared in another manner phthisis shows its dependence upon indoor conditions. In England previously to 1865 the phthisis death-rate was greater among females than among males, the difference gradually diminishing until the mortality among each sex was equal. Since 1866 the mortality has continued to diminish in both sexes, but in a larger proportion amongst females and males. The male rate being taken at 1000 the female rate in successive decennia and onwards has been 1076 (1851-60), 1006 (1861-70) 918 (1871-80), 871 (1881-90), 802 (1891), 813 (1892), 797 (1893), 779 (1894), 795 (1895), 767 (1896), 758 (1897), and 747 (1898). This greater proportionate diminution in the phthisis mortality amongst females, the more indoor of the two sexes, is significant of the improvement of dwellings and more so when it is realised that the greatest diminution has taken place between the ages of 15 and 45 years, the child-bearing and the child-rearing period, when the woman is most indoor. Dr. Arthur Ransome in his researches on tuberculosis[10] has also shown that in country towns where the men are chiefly occupied out of doors and the women indoors the death-rates from phthisis of females exceed those of males, and that in manufacturing towns where the men are mostly attracted to indoor employments the excess is upon the male sex.

Density in Cubic Space.

Upon square space, as we have seen, we may have increasing density due to the crowding of cities with towns, of towns with quarters, of quarters with street blocks, and of street blocks with houses. It would not be wise to conclude that density upon square space is a thing to be ignored or to be belittled to the extent of minimising the immense value of separating towns or boroughs from each other by parks and commons, quarters by squares and gardens, street-blocks by broad streets and avenues, and houses by sufficient rear-spaces. The proportionate amount of open square space to the covered superficial area of towns and quarters has not received any exact estimation. The width of streets

[8] Annual Report for 1890, Dr. G. P. Bate, medical officer of health of St. Matthew, Bethnal Green.

[9] Supplement to the Forty-fifth Annual Report of the Registrar-General, 1885.

[10] Weber Parkes Prize Essay, 1897.

and size of rear-spaces, both of great influence upon health as shown by large insanitary areas, will be considered later.

Density in cubic square deals with street blocks that may be crowded with houses, houses with dwellings, dwellings with rooms, and rooms with persons. The first three are questions of structure embracing the size and disposition of rooms, dwellings, houses, and street blocks. On the other hand, the crowding of persons into these is a question of *usage* upon which some statistics are available.

Persons per house.—The varying size of houses and the greater variation introduced by the modern "flat" method of construction has destroyed any value that comparative statistics as to the number of persons per house may have possessed. This applies particularly to London and some other large cities, and therefore we must fall back upon old and well-known statistics.

That disease depending solely upon personal infection prevails in proportion to the increased number of inmates in a house is demonstrated by the following table of typhus mortality in Berlin in 1880[11] in proportion to density of population in houses:—

TABLE VII.

Number of deaths from typhus.	Number of city districts.	Mean number of inmates of houses.
0	83	49·9
1	29	62·7
2	51	64·5
3	22	74·4
4	18	77·1
5	5	77·4
6-9	6	91·5
10-13	2	98·5

We know that pulmonary phthisis is most prevalent in large towns, in the most densely built parts of a town, and in the most densely populated areas of those parts. In dwelling-houses the effects of crowding received the clearest exposition in the army medical reports and inquiries relating to barracks. The mortality from phthisis in the British army was:[12] from 1830 to 1846, 7·86 per 1000 of strength; from 1859 to 1866, 3·1 per 1000; from 1867 to 1871, 2·6 per 1000; from 1872 to 1880, 2·3 per 1000; from 1879 to 1884, 2·08 per 1000; from 1886 to 1887, 1·47 per 1000; and in 1888, 1·23 per 1000.

It was in 1858, the period when the great fall in mortality took place, that the celebrated report of the Royal Commission on the Sanitary Condition of the Army was issued. The mortality from lung diseases was found to vary greatly in four branches of the army, namely:—

TABLE VIII.

——	1837-46, 10 years.	1864-70, 7 years.
Household cavalry	6·28	3·76
Cavalry of the line	5·65	1·41
Foot Guards	11·9	2·30
Infantry	7·75	2·12

The only decided difference between these various arms was the condition of overcrowding in barracks, and the only decided difference made between the earlier and the later periods was the increased cubic space per head. The same prevalence of lung diseases was found in most of the European armies and particularly in those portions stationed in large cities.

Persons per dwelling.—Dr. J. B. Russell has shown[13] that a diminution of the size of dwellings tends to correspond with an increase in the mortality, particularly when accompanied by an increase in the number of persons per room, and that the progress-increase of mortality coincides with the progressive increase of the percentage of population living in dwellings of one room, as shown by the following table:—

TABLE IX.—*Showing the Relation of the Death-rate to Dwelling Accommodation in the Eight Principal Towns of Scotland.*

Locality.	Death-rate 1871-1880.	Persons per acre, 1881.	Rooms per dwelling.	Persons per dwelling.	Percentage of population living in dwellings of—				
					One room.	Two rooms.	Three rooms.	Four rooms.	Five or more rooms.

Paisley ...	27·8	16	2·42	1·984	23·0	44·1	14·7	6·8	11·4
Glasgow ...	28·6	84	2·34	2·054	24·7	44·7	16·0	6·1	8·5

The towns fall into two well-marked sets of four, the four upper with death-rates below 24 per 1000 and dwellings of from three to five rooms, the four lower with death-rates above 25 per 1000 and dwellings of less than three rooms, and in this group the death-rate rises *pari passu* with the diminution in the size of the average dwelling.

Dr. Anderson, the medical officer of Dundee, found in 1884 in that city that the mortality in dwellings of one room was 21·4 per 1000, of two rooms 18·8, of three rooms 17·2, and of four rooms and upwards 12·3 per 1000, and as deaths in workhouses, hospitals, and other institutions were omitted the true death-rate of the smaller dwellings would be relatively higher still, as the general death-rate of Dundee was 20·7 per 1000. Dr. J. B. Russell again by detailed inquiry also worked out the mortality from various causes, and the mortality from all causes in three classes of dwellings, small, medium, and large, in Glasgow for the year 1885, and the results are set out in the following table:—

TABLE X.—*Death-rates from Various Causes in Various Sized Dwellings in Glasgow in 1885.*[14]

Causes of death.	Dwellings of 1 and 2 rooms.	Dwellings of 3 and 4 rooms.	Dwellings of 5 rooms and upwards.
Zymotic diseases (including diarrhœa)	4·78	2·46	1·14
Acute diseases of the lungs (including consumption) ...	9·85	6·89	3·28
Nervous diseases and diseases of nutrition of children... ...	4·80	2·35	0·91
Accidents and syphilis in children	0·32	0·11	—
Miscellaneous unclassified diseases...	7·99	7·64	5·90
Total (all causes)	27·74	19·45	11·23

Taking the death-rates in the large dwellings as the standard the death-rate from zymotic diseases was two-fold greater in the medium and four-fold in the small; from lung diseases two-fold greater in the medium and three-fold in the small; and from diseases of nutrition in children under five years of age (convulsions and other nerve affections, atrophy, wasting, and premature birth) over two and a half-fold greater in medium and over five-fold greater in small dwellings of one and two rooms.

[14] On the "Ticketed Houses" of Glasgow, Proceedings of the Philosophical Association of Glasgow, 1888-89.

A comparison between the increasing density of persons in dwellings and consumption in the Duchy of Baden is stated to have given the following results :—[15]

TABLE XI.

Per 1000 inmates.	Consumption mortality.

,, 5, 470 ,,	3·23 ,,

Persons per room.—In dealing with persons per room we have a basis of which the limits are not so wide, and although an international basis cannot be defined it may be said that in England the limits lie between 600 and 1400 cubic feet, but mainly between 800 and 1200, and average perhaps somewhere near 1000 cubic feet per room, in dwellings of less than five rooms. If one regards as overcrowded the dwellings in which the number or inhabitants exceeds double the number of rooms the following are the results in different cities of Europe :—[16]

TABLE XII.

City and date.	Population.	Overcrowded population.	Percentage overcrowded.	Mortality of whole city.
London (1891)	4,211,743	830,182	20 per cent.	21·4
Paris (1891)	2,424,705	331,976	14 ,,	21·6
Berlin (1885)	1,315,387	363 960	28 ,,	24·6
Vienna (1890)	1,364,548	387,000	28 ,,	24·6
Budapest (1891) ...	468,759	348,609	74 ,,	28·0
St. Petersburg (1890)	956,226	442,508	46 ,,	23·4

It is probable that the greater attention paid to the sanitation of houses in London as compared with Paris may in some measure account for the mortality not exceeding that of Paris, where the overcrowding was less in 1891 than in London at the same census date.

Dr. Korosi has disputed the interpretation placed upon the high percentage of overcrowding in Budapest and has pointed out that in Budapest[17] only rooms (*chambres*) in a dwelling (*logement*) were included, whereas in Paris compartments (*pièces*) such as lobbies, &c., in a suite or flat (*appartement*) were included, so that the percentage of overcrowding in Budapest should be considerably reduced and that of Paris somewhat increased. Dr. Jacques Bertillon has further pointed out that it is probable that the census enumeration of overcrowding in London is understated on account of the indefiniteness of the question as to rooms and of omissions to reply.[18]

Bearing these points in mind there is a remarkable coincidence between the gradation of overcrowding and of mortality in the above table, and, omitting the first and the last, this is particularly noticeable in the four great cities of the continent in which a similarity in the structure of buildings prevails. This is an important point bearing upon one of the disadvantages attending the continental mode of construction now coming into vogue in London. The mortality in Leipsic in 1875 and 1876 in proportion to density of persons per room according to the census of Dec. 1st, 1875, was as follows :—

TABLE XIII.

Streets with a mean population of—	Of 100 died yearly. Under one year.	Of 100 died yearly. Over five years.	All ages.
			Per cent.
0–1 inmates in each room.	11	1·0	1·1
1–1·5 ,, ,, ,,	25	1·1	1·8

2–2·5 ,, ,, ,,	34	1·4	2·6
2·5–3 ,, ,, ,,	33	1·3	2·7
Over 3 ,, ,, ,,	42	1·8	3·4

The figures show that when the number of inmates per room increased from one to three, that is, more than treble, the death rate at all ages also trebled and the death-rate under one year quadrupled.[19] The later experience of Glasgow[20] of the effect of room-density upon tuberculous diseases is that in each district of the city where the phthisis death-rate exceeds the mean, there also the room-density is in excess, and concurrently with the rise in the minimum cubic space per adult inmate to 460 cubic feet in 1890 and the increase in the minimum size of rooms by the Building Regulations Act of 1892, and with other factors, the phthisis death-rate is decreasing, but the rate of decrease is greater in districts which have a concurrent decrease in room-density.

With reference to overcrowding of air-space in dwelling-rooms in the metropolis Mr. Shirley Murphy has shown[21] that : 1. In London sanitary districts the death-rate from phthisis increases *pari passu* with the increase in the proportion of population living more than two in a room, in tenements of less than five rooms. 2. In these same districts, whilst overcrowding is associated with a tendency of the population to die from disease generally, this tendency is not manifested in the case of every disease. The mortality from cancer does not appear to have any relation whatever to overcrowding, that of diarrhœa and the principal zymotic diseases (excluding diarrhœa) is not particularly apparent, the mortality from tabes mesenterica shows a slight correspondence with the degree of overcrowding, that from tuberculous meningitis shows a little more, but the mortality from phthisis closely corresponds with the degree of density of persons per room. 3. In these same districts the increase of mortality from all causes in proportion to the overcrowding manifests itself at the same ages as the increase of mortality from phthisis—namely, 25, 35, 45.

It is recognised that the most important in the spread of pulmonary tuberculosis is predisposition, and predisposition can be acquired as well as be innate, and, further, that by hygienic measures the acquired predisposition and the innate disposition, and even the communicable entity of the disease itself, can be so controlled as to be kept in abeyance and even to be permanently subdued. It is further recognised that the conditions under which it may be acquired are residence in impure air, particularly such as is not renewed often enough, crowding of persons together, absence of sunlight, and dampness. In susceptibility to phthisis the power of resistance appears to be even more important than the power of infection, or, in other words, the prevention of loss of vitality or energy is most important.

Persons per cubic space.—In cities the average dwelling space of the inhabitants has a closer relationship to their health than any other condition of health which is capable of statistical expression.[22] Hence I have dwelt at some length upon density of population. If we could obtain a classification of only a portion of the population according to the amount of measured cubic space occupied and the causes of mortality we should, perhaps, be able to draw more definite and exact conclusions still.

Typhus fever was formerly very prevalent under conditions of gross overcrowding, and not only typhus fever but other

infectious diseases tend to diminish in prevalence with increase of cubic dwelling-space.

The phthisis death-rate shows a close relationship to density of persons in cubic space, and phthisis appears to stand almost in the same relationship to respiratory pollution as typhoid fever does to filth pollution. The respiratory diseases apart from phthisis are also influenced by impurities of the air and afford some measure of their effects, just as diarrhœal diseases, apart from typhoid fever, are regarded as bearing a relationship to impurities of the soil.

II.—EFFECTS UPON HEALTH OF CERTAIN KINDS OF HOUSES AND DWELLINGS.

It has already been mentioned that the crowding of cities with townships and townships with quarters are faults of municipal planning. The crowding of quarters with street-blocks and of street-blocks with buildings brings us to the consideration of streets and houses, with particular reference to the dwellings they contain and the health of the inmates.

Street blocks of houses.—This is a convenient term for the blocks of land isolated from each other by the surrounding streets and which are divided into the plots upon which the buildings stand. The effects of insufficiently separating street blocks from each other—that is, of allowing streets to be made too narrow—displays itself as one of the causes of unhealthiness of insanitary areas, the statistics of which have been considered, and that narrowing of streets directly tends to increase the mortality of a population will be seen from some statistics when considering back-to-back houses. Street blocks contain various kinds of buildings for commercial and for residential purposes and some types of the houses and dwellings have been subjected to statistical inquiry—for instance, back-to-back houses, stable-dwellings, tenement houses, cellar dwellings, and "flat" houses.

Back-to-back houses.—The results of statistical inquiries into the effects of back-to-back houses as constructed in the North of England vary in some minor points but agree in the main. The first statistics published were those of certain districts of Salford from 1879 to 1883 by Dr. Tatham, and they showed that parallel with the increase in the proportion of back-to-back houses in the groups selected the death-rates from all causes, pulmonary diseases, phthisis, and the principal zymotic diseases, and diarrhœa taken separately also progressively increased. Dr. Niven later confirmed these conclusions by statistics relating to the old township of Manchester from 1891 to 1894, and found further that with regard to age that in infancy and in advanced years there was also an excess of mortality in the back-to-back houses. The careful statistics of Mr. Herbert Jones from 1887 to 1892, comparing "through" houses in Saltaire with back-to-back houses in Shipley, showed that in the latter the mortality per 1000 from all causes was over one-third greater than in the former, from lung diseases nearly one-half greater, from zymotic diseases over one-half greater, and from diarrhœa alone over two-thirds greater. Collaterally they also furnished the required proof that in proportion to the disease in the width of streets the mortality progressively increases amongst a like population living under similar conditions. Dr. Arnold Evans also obtained confirmatory results of the increase of mortality with the increase in the population of back-to-back houses in the wards of Bradford in 1890–1892. The statistical results obtained by these medical officers of health are all set out in the table below, to which is also added the results I have obtained from the statistics of stable-dwellings, a class of dwellings similar in construction.

These statistics show that the mortality from all causes increases with the increase in the number of back-to-back houses and that the mortality from lung diseases, phthisis, the principal zymotic diseases, and diarrhœa alone increases in a similar manner, and that as the width of the streets diminishes the increase in the mortality from all causes, and these special causes, becomes more and more marked.

Stable-dwellings.—There are certain insanitary conditions that attract attention in mews. The houses are usually constructed in two storeys, with stables at ground level and dwellings over, and, like back-to-back houses, have only one front, the other three sides being generally without windows or doors and without back- or side-yards. The dwellings are frequently, in the absence of plaster ceilings and the presence of ill-fitting floor-boards, or by means of inside staircases, more or less open to the stables below. Beneath the dwelling-rooms are horses with their litter and manure, drain gullies (although these are generally properly trapped), and often water-closets under the stairs, sometimes unventilated. These conditions would incline one to expect that the mortality would indicate marked excess in the same causes of death as has been shown by observers in the case of back-to-back houses. And the more so because the roadways of the larger mews, formerly maintained by the owners, have been gradually left to the maintenance of public authorities, a course leading to the prohibition of placing manure and domestic refuse outside the stable-house on what has become public way and tending towards its retention under the dwelling-rooms.

In 1891 an inspection was made of the mews and stables in St. Pancras, and from the notes then made I have been able by means of careful compilation and revision to obtain

Gordon Smith, F.R.I.B.A., Local Government Board, 1888. † Transactions of the Sanitary Institute, vol. xvi., 1895. ‡ Public Health, vol. v., 1892-93. § Transactions of the Epidemiological Society, vol. xv., 1895-96. ‖ In course of publication.

comparable returns of these premises. The number of adults and of children under 10 years living in each dwelling over the stables was also ascertained, so that an enumeration of the population was made in the same year as the census was taken. In conjunction with the census returns this renders it possible to compare the population under 10 years and 10 years and over living (1) in stable-dwellings, (2) in the whole of St. Pancras, and (3) in the whole of London. The deaths (corrected for public institutions) for the three years 1890, 1891, and 1892 were also extracted, and these also are comparable with the returns of St. Pancras and of London for the same three years. The superintendent registrar of St. Pancras, Mr. J. Stevens, has kindly extracted and supplied me with the number of births, and these, again, are similarly comparable. With the aid of these statistical bases and the kind assistance of Mr. S. M. Kaka, D.P.H., medical officer of health of Karachi, I have been able to prepare a series of tables that have been condensed into conveniently comparable compass and are attached hereto.

In examining the tables of population and mortality the first point that attracts attention is that in the stable-dwellings 34·9 per cent. of the population is under 10 years of age, compared with 21·6 per cent. in all St. Pancras and 22·7 in all London. The next thing is that the birth-rate is half as high again over stables as in the whole of St. Pancras and London. It is possible that this proportion is slightly exaggerated owing to the fact that whereas the population and the deaths in stable-dwellings were extracted for each dwelling, the births have been extracted in bulk for each mews, and a few houses not strictly part of the mews may have been included. On the other hand, this suggests that the death-rate of infants under one year per 1000 births, that stands at 193 in stable-dwellings as compared with 160 in St. Pancras and 157 in London, may be actually higher than it appears—possibly 200 or more per 1000 births. The fact remains that there is a high infantile mortality. The main causes of infantile deaths in stable-dwellings are the following, set out in table form and compared with St. Pancras and London:—

TABLE XV.—*Causes of Deaths under 10 years of age: mean of three years, 1890–91–92.*

Causes.	Mean number.	Stable-dwellings.		St. Pancras	London.	
		Death-rate per 1000 births.	Number.	Death-rate per 1000.	Number.	Death-rate per 1000.
Suffocation	1·6	12·3	48·0	6·8	1657·6	4·9
Bronchitis and pneumonia	8·0	61·9	210·3	29·9	3930·3	29·8
Measles and whooping-cough	1·6	12·3	81·3	11·5	1602·6	12·1
Diarrhœa	3·3	25·5	115·3	16·4	1857·0	14·1
Total of above ...	—	112·0	—	64·6	—	60·9

The total infantile mortality in stable-dwellings from these causes is nearly double that of St. Pancras and of London. Incidentally, compared with London in 1890–92, suffocation as a mode of death appears to have been more favoured in St. Pancras and most favoured in stable-dwellings. Measles and whooping-cough mortalities scarcely differ. Diarrhœa shows somewhat under a double death-rate, and bronchitis and pneumonia somewhat over a double death-rate, compared with St. Pancras and London.

The death-rate of infants under one year per 1000 of total population at all ages was in stable-dwellings 9 04, in St. Pancras 4·80, and in London 4·92, again showing a heavy infantile mortality, and the inference that a large proportion of the population consists of children. This is corroborated by the actual number of persons under 10 years of age compared with the number at 10 years and over, the proportions being, in stable-dwellings 100 to 186, in St. Pancras 100 to 361, and in London 100 to 341. The death-rate under 10 years of age in London is 38 7 per 1000 of population under 10 years, and 1 per 1000 higher in St. Pancras, and 2·3 per 1000 higher in stable-dwellings. Over 10 years of age per 1000 of population the mortality in London is 15·5, 1·6 higher in St. Pancras, and 4·6 higher in stable-dwellings.

In order to compare stable-dwellings with back-to-back houses the following table (XVI.) of mortality has been drawn.

Back-to-back houses show an excess in mortality from all causes, from pulmonary diseases, from phthisis, from the principal zymotic diseases, and from diarrhœa, taken separately. Stable-dwellings show an excess of mortality from the same causes, but not in the same proportion. The death-rate at all ages in the stable-dwellings is 5·4 above that of St. Pancras, and 7·4, or nearly one-third more, above that of London. That this is not mainly due to the high infantile mortality is seen from the fact that whereas the mortality under 10 years of age is 2·3 above that of London, the mortality of 10 years and over is 4·6 above that of London per 1000 of population living between the two respective age periods. The death-rate at all ages from the "principal zymotic diseases" is the same in St. Pancras and London—namely, 2·69 per 1000; but stable-dwellings show a rate 2·12 higher—namely, 4·81 per 1000. The diarrhœa death-rate, which appears as 0·62 per 1000 in London and 0·53 in St. Pancras, is three times as high in stable-dwellings—namely, 1 66 per 1000 population. Tuberculous diseases are 0·23 higher in St. Pancras than in London, and 0·20 higher in stable-dwellings than in St. Pancras, phthisis 0 20 and 0·11 higher per 1000 of population. One might expect higher results in back-to-back type of houses. Respiratory diseases show a high death-rate, 8·17, over stables, compared with 5 25 in St. Pancras and 4·93 in London. The rate is 3·24 higher than in London, but bronchitis and pneumonia alone show a still higher rate, approaching twice that of London. In the Registrar-General's last decennial report the mortality of cabmen and carmen from diseases of the respiratory system is given as 128 and 170 respectively, when 100 is taken as the standard of all occupied males, and the comparative figures for all engaged in various branches of transport service by road, rail, river, and sea is 147; but that the high rate in stable-dwellings is not due solely to occupation is shown by the high mortality from bronchitis and pneumonia amongst the home-dwelling infants. This is not due to poverty, as cabmen and carmen are not indigent as a class; the families of even the poorer are fairly cared for in food and clothing, and the better off are well fed and well clothed. If the last three double rows of

Sykes, St. Pancras, 1890–92.	Stable-dwellings	2766	27·4	8·0	2·28	4·8	1·66	193·3
	St. Pancras...	234,379	22·0	4·8	2·17	2·7	0·53	160·0

* Joint Report of Dr. Barry and Mr. P. Gordon Smith, F.R.I.B.A., Local Government Board, 1888. † Transactions of the Sanitary Institute, vol. xvi., 1895, p. 254. ‡ Public Health, vol. v., 1892–93, p. 347.

figures are taken and the excess mortality in the groups of back-to-back houses and in stable-dwellings over the groups of the other houses with which they are respectively compared are set out in tabular form the proportionate differences become apparent:—

TABLE XVII.

Locality.	All causes.	Pulmonary diseases, excluding phthisis.	Phthisis.	Principal zymotic diseases.	Diarrhœa.	Under 1 year of age.
Manchester ...	6·7	1·5	0·3	2·0	1·0	20·6
Shipley	5·5	1·5	0·7	0·6	0·1	—
St. Pancras ...	5·4	3·2	0·1	2·1	1·1	33·3

It is seen at once that in stable-dwellings there is an excessive mortality from pulmonary diseases and in infantile mortality and a lesser excess from phthisis. The probability appears that the vicissitudes of temperature in the occupations of the adults and the construction of the homes of the infants in stable-dwellings are prominent factors in the causes of mortality. Some stables are draughty during cleaning time when the stable doors and loft doors are open. Some stable roofs have no ceilings below to equalise the temperature. Some also have skylights over the back dwelling-rooms, although seldom open, and there are air-bricks in the back walls of some stables. Yet they show a high zymotic death-rate per 1000 of population, the individual diseases appearing as follows:—

TABLE XVIII.

Locality.	Small-pox.	Scarlet fever.	Diphtheria.	Fevers.	Measles.	Whooping-cough.	Diarrhœa.	Total.
Stable-dwellings	—	0·22	1·19	—	0·72	0·94	1·66	4·81
St. Pancras	—	0·18	0·48	0·12	0·61	0·63	0·53	2·69
London	—	0·21	0·37	0·13	0·67	0·68	0·62	2·69

The death-rates are very high from diarrhœa and diphtheria

and high from whooping-cough, even when a number of unhealthy conditions are absent. For stables have no underground rooms or cellars and no ground floors below the level of the street and there is less liability to the rise of ground air under the dwelling-rooms and to the dampness of walls of the dwelling-rooms by capillarity.

The conclusions to be drawn are that the occupants of stable-dwellings have a high birth-rate and a high mortality under one year and at all ages and high death-rates from pulmonary diseases, both of infants and adults, and from the zymotic diseases, especially diarrhœa and diphtheria. These point to the effects of the vicissitudes of temperature affecting adults and unhealthy conditions at home affecting young children.

ON THE INFLUENCE OF OZONE ON THE VITALITY OF SOME PATHOGENIC AND OTHER BACTERIA.[1]

BY ARTHUR RANSOME, M.D. CANTAB., F.R.C.P. LOND., F.R.S.,

AND

ALEXANDER G. R. FOULERTON, F.R.C.S. ENG.

THE influence of ozone on the vitality of bacteria is a matter which has received the attention of several investigators, but on reviewing the records of the results which have been arrived at it is obvious that such results have not always been consistent. We determined, therefore, to investigate this question anew, in the hope of being able to come to a definite conclusion. The matter seemed to us to be one of considerable importance, since if ozone were possessed of the bactericidal properties which have been attributed to it by more than one investigator the gas might prove of much value in solving one of the most unsatisfactory problems which have to be dealt with in the practice of modern sanitation—that is to say, the disinfection of rooms after the occurrence of infectious disease. Ozone can now be conveniently produced in large quantities, and, if efficient, would be admirably adapted to effect the purpose in view.

The question of the bactericidal action of ozone was especially brought into prominence by the classical work of Downes and Blunt, embodied in communications made to this society in 1877 and 1878.[2] Working with impure cultures of bacteria, these investigators showed that direct sunlight in the presence of atmospheric air was capable in some cases of preventing in greater or less degree, or in other cases of absolutely inhibiting, the growth of the particular bacteria experimented with; and that not only might growth be inhibited but that the bacteria themselves might be actually destroyed. Downes and Blunt further showed that so far as the destruction of bacteria is concerned the blue and violet rays of the spectrum are more effective than the red rays, that the interposition of a layer of water is sufficient to protect the bacteria to a certain extent, and that direct sunlight acting *in vacuo* may fail to destroy sporing bacteria.

Whilst this work of Downes and Blunt has been fully confirmed and amplified in certain directions by the work of others no satisfactory explanation has yet been arrived at as to exactly how it is that bacteria are destroyed under these conditions. The explanation that the result is a direct effect of the sun's rays—of heat—has been shown to be untenable; and it has therefore been assumed that the destruction is effected by chemical rather than by physical action—that it results from an active oxidation of the substance of the bacteria by ozone produced by the action of sunlight on atmospheric air. Others have regarded peroxide of hydrogen as the active agent.

Amongst the experiments which have been carried out in order to test this assumed bactericidal action of ozone we may particularly mention those of Chapuis,[3] Sonntag,[4] and Ohlmüller.[5] Chapuis filtered air through cotton-wool and then exposed plugs of the wool with the contained bacteria to the action of ozone. The plugs were afterwards incubated in a nutrient wort solution which remained sterile. Control plugs of the wool which had not been subjected to the action of the ozone gave rise to a free growth of bacteria when incubated in the same medium. Sonntag and Ohlmüller's experiments, on the other hand, seemed to show that ozone in the dry state had little or no action on bacteria but was capable of destroying them when passed through water containing them. Thus bacillus anthracis suspended in distilled water was destroyed after air containing 9·6 milligrammes of ozone per litre had been passed through the mixture for 10 minutes. A sporing culture of the same bacillus was killed by passing air containing 15·2 milligrammes of ozone per litre through the water for 10 minutes. If, however, organic matter, such as blood serum, were added to the water the results were different; and it seemed that under these latter conditions the most part of the ozone was expended in oxidation of the dead organic matter present, whilst the bacteria were little if at all affected.

Our experiments were planned with the view of ascertaining whether ozone applied in large quantities, either in a mixture with atmospheric air or with pure oxygen, has in reality a destructive influence on bacterial life, and especially whether it has any such influence under conditions which would enable it to be used for practical purposes of disinfection.

The experiments have included the testing of the action of ozone (1) on the vitality of certain pathogenic and saprophytic bacteria; and (2) on the virulence of one pathogenic species. For the purposes of the latter test we decided to test the action of the gas on bacillus tuberculosis, an organism which is known to be readily affected by the direct action of ordinary chemical agents and one which numerous experiments would lead us to believe is very susceptible to the action of direct sunlight (Koch,[6] Ransom and Delépine,[7] and Jousset).[8]

EXPERIMENT I.

In our first experiment culture tubes with "sloped" surface of nutrient agar or gelatin were inoculated with various bacteria; a mixture of atmospheric air and ozone was passed continuously over the inoculated surface for a period of at least four hours, commencing 24 hours after the tubes were inoculated. The tubes were then incubated at appropriate temperatures and the result compared with that obtained in control tubes which had been inoculated from the same stock cultures at the same time.

In detail the following was the procedure carried out. The culture tubes were of the ordinary 15 × 2 centimetre size, into the sides of which short pieces of 0·75 centimetre calibre glass tubing had been blown in such a way that they opened into the lumen of the culture tubes about three centimetres from the bottom and just above the lower level of the sloped nutrient surface and allowed the ozonised air to escape after passing over the bacteria. The culture tubes were closed at the upper end by a piece of cork through which passed a short length of the 0·75 centimetre tubing, which formed the inlet for the ozonised air. The inlet and outlet tubes were loosely plugged with cotton wool and by means of them and short lengths of indiarubber tubing the culture tubes could be connected up in series and sterile ozonised air drawn over the inoculated surfaces. Such culture tubes were inoculated with the following bacteria:—Glycerine-agar tubes: Nos. 1 to 6 with bacillus tuberculosis and Nos. 7 and 8 with bacillus mallei. Nutrient-agar tubes: Nos. 9 and 10 with bacillus diphtheriæ and Nos. 11 and 12 with bacillus anthracis (sporing). Nutrient-gelatin tubes: Nos. 13 and 14 with bacillus typhosus, Nos. 15 and 16 with micrococcus melitensis, and Nos. 17 and 18 with micrococcus candicans.

The tubes were then arranged in two series, those numbered from 1 to 12 being connected up in one series and those numbered from 13 to 18 in another. The two series of tubes were then placed in a room of about 900 cubic feet capacity and ozone was generated in the air of the room by means of four small "ozonisers," a three-inch spark Ruhmkorff coil and an accumulator battery being

used. The "ozonisers" were kept working for four hours, during the whole of which time ozonised air was slowly aspirated through the tubes. At the end of four hours the arrangement of the tubes was altered; a fresh series, including those numbered from 3 to 12 and from 15 to 18, being connected up, and pure oxygen charged with ozone was forced through the tubes for a period of 30 minutes. During this half hour ozonised air was still being drawn through No. 13 and No. 14. The culture tubes were then incubated, No. 1 to No. 12 at 37° C., and No. 13 to No. 18 at 22° C., the respective control tubes being incubated with them. The result of the experiment was that in the case of two out of the seven species tested there seemed to have been some slight retardation of growth as the result of the exposure to the ozone; that is to say, in the case of one or both of the duplicate tubes containing bacillus mallei and bacillus diphtheriæ the growth of the experimental cultures seemed at first to be rather slower than it was in the corresponding control tubes. But at the end of eight days' incubation all difference between the experimental and control tubes had disappeared and growth was equal in both sets; and in further experiments this effect was not obvious. In the case of the other five species not the slightest effect could be observed as the result of the exposure. The experiment was carried out under conditions which, although they might approximate to those which would prevail in the actual use of ozone as an aerial disinfectant, were not adapted to test the action of ozone on bacteria apart from an important disturbing factor. The bacteria were submitted to the action of ozone in the presence of a large amount of dead organic matter, and it was quite conceivable that such an amount of the ozone might have been decomposed in the oxidation of the dead organic matter that but little had been left to exert any action on the living bacteria.[9]

EXPERIMENT II.

In this experiment we endeavoured to test the action of ozone on the bacteria in the absence—so far as we could insure the condition—of dead organic matter. The same culture tubes were used, but instead of inoculating agar or gelatin nutrient surfaces we inoculated small blocks of plaster-of-Paris from stock cultures of the various bacteria tested. These plaster-of-Paris blocks when inoculated were placed in the culture tubes and the inlet and outlet tubes were plugged with fine Italian asbestos fibre instead of with cotton-wool. And instead of passing the same current of ozone over a series of tubes in succession we connected each tube separately with a main feeding pipe with lateral branches, the respective tubes being held in contact by pieces of indiarubber tubing. Thus each culture tube had a fresh supply of ozone. Ozone was generated as before and passed over blocks inoculated from stock cultures of the following: (1) staphylococcus pyogenes aureus; (2) streptococcus pyogenes; (3) micrococcus melitensis; (4) Bacillus mallei; (5) bacillus diphtheriæ; (6) bacillus anthracis (from sporing culture); (7) bacillus typhosus; (8) bacillus coli communis; (9) bacillus pyocyaneus; (10) bacillus pneumoniæ (Friedländer); (11) bacillus prodigiosus; and (12) saccharomyces albicans.

Duplicate tubes were inoculated with each organism and a continuous current of air was pumped over the ozoniser, which was inclosed within a glass cylinder connected with the main feeding-tube and then through the culture-tubes for a period of 30 minutes. The actual amount of ozone used was not estimated, but iodide of potassium and starch paper held over the outlet tubes gave a positive reaction within 60 seconds of the commencement of the experiment. The small plaster-of-Paris blocks were then shaken up in tubes containing 3 cubic centimetres of nutrient broth, from the broth tubes loopfuls were transferred to other media, and the growth obtained after incubation compared with the growth on control tubes.

The results obtained on incubating the sub-cultures made it evident that none of the bacteria had been affected by the ozone in such a way as to impair either their capability of growth or in the case of the two chromogenic bacteria their function of pigment production. The pathogenic action of a broth sub-culture of bacillus mallei after the ozonisation was tested by intra-peritoneal inoculation of a male guinea-pig; an ordinary infection with characteristic lesions followed, the animal dying within 48 hours.

[9] We are indebted to Mr. Bridge, chemist, of Bournemouth, for assistance in the working of the ozonising apparatus used in carrying out this experiment.

EXPERIMENT III.

We now decided to subject the bacteria to a rather more severe test than had been involved in the two preceding experiments. The ozone was produced by passing oxygen under pressure from a cylinder over a powerful "ozoniser" inclosed within a glass cylinder, and then into the main feeding tube, as in the previous experiment. The current used was an alternating one direct from the street main. Small pieces of porcelain were, after inoculation with the following bacteria, placed in the culture tubes: (1) sarcina ventriculi; (2) micrococcus melitensis; (3) micrococcus candicans; (4) bacillus mallei; (5) bacillus diphtheriæ; (6) bacillus anthracis (from 24-hour old culture in broth, non-sporing); (7) bacillus anthracis (from old sporing culture on potato); (8) bacillus typhosus; (9) bacillus coli communis; (10) bacillus pyocyaneus; (11) bacillus pneumoniæ; and (12) bacillus prodigiosus.

Duplicate tubes of each species were used for the experiment, the first attempt to carry out which resulted in failure owing to the action of the ozone on the pieces of india-rubber tubing by which the branches of the main feeding-tube and the inlets into the culture tubes were held in contact. Before the mixture of ozone and oxygen had been passed into the series of culture tubes for 90 seconds every piece of indiarubber tubing was cut through as if with a knife. The joints were therefore made with pieces of bored cork and the experiment repeated. The mixture of ozone and oxygen was passed through the tubes at the rate of 1·5 litre per minute for a period of 30 minutes; the yield of ozone, as estimated by titration with $\frac{N}{10}$ iodide solution, amounted to 0·072 gramme per minute. The percentage amount of ozone was, therefore, about 2·4 by volume. At the end of 30 minutes the pieces of porcelain were dropped into tubes of nutrient broth and incubated. On comparison with the various controls it was obvious that the ozone had not affected the bacteria in such a way as to impair either their capability for growth or, in the case of the chromogenic organisms, their power of producing pigment. The broth sub-culture of bacillus anthracis (non-sporing) after 48 hours' incubation at 37° C. was tested on a white mouse and proved to be of normal virulence, 0·25 cubic centimetre of the broth culture injected into the peritoneal sac killing the animal within 24 hours in typical fashion.[10]

EXPERIMENT IV.

Although it seemed to have been conclusively proved by the experiments of Ohlmüller, already referred to, that ozone was capable of considerable bactericidal action when the organisms were suspended in certain fluids, we determined to carry out a single experiment, using milk as the medium. We used milk because we considered that it would, as containing a large quantity of organic matter, test the bactericidal action of the gas severely.

Five flasks, each containing 125 cubic centimetres of milk, were prepared as follows:—Flask 1 contained sterilised milk which had been inoculated with a culture of bacillus anthracis (sporing). Flask 2 contained sterilised milk which had been inoculated with a non-sporing culture of bacillus anthracis. Flask 3 contained ordinary fresh unsterilised milk, to which a quantity of a broth culture of bacillus prodigiosus had been added. Flask 4 contained ordinary fresh unsterilised milk. Flask 5 contained a sample of commercial "sterilised" milk which had "gone bad" owing to the presence in pure culture of an anaerobic, sporing, butyric acid forming bacillus. A current of oxygen containing the same proportion of ozone as that used in Experiment III. was passed through the milk in each of the flasks for a period of 20 minutes at the rate of 1·5 litres per minute. Loopfuls of milk were then taken from each flask, transferred to various culture media, and incubated under both aerobic and anaerobic conditions; the flasks with the bulk of the milk still remaining in them were also incubated.

In the result it was found that the contents of Flasks 1, 2, and 5 were sterile of bacteria. The milk used for Flask 3 and Flask 4 was taken from the same sample, and on incubation of the sub-cultures after ozonisation a growth of a mould-fungus was obtained from each flask; from Flask 3 a very free growth of the mould was obtained, but neither bacillus prodigiosus or any other bacterium; from Flask 4 a

[10] We are indebted to Mr. Wood Smith, F.I.C., for assistance in the working of the ozonising apparatus used in this experiment.

few colonies of a coccus were obtained in both aerobic and anaerobic cultures in addition to the mould which was present apparently in less quantity in the contents of Flask 4 than it was in the contents of Flask 3. In the case of the sub-cultures from Flask 3 the growth of the mould was very rapid and soon covered the surface of the medium, and so possibly checked the growth of the coccus which appeared on the sub-cultures from Flask 4, in which the mould growth was less abundant. A loopful of the milk used for Flask 3 and Flask 4 taken before ozonisation and smeared over nutrient agar gave, on incubation at 22° C., a large number of colonies of different bacteria; and it was apparent that the exposure to ozone had resulted in the destruction of a large majority of these, although complete sterilisation was not obtained as in the case of Flasks 1, 2, and 5. At the end of the experiment the milk in Flasks 1, 2, 3, and 4, although not changed in appearance, had acquired an extremely disagreeable taste and smell, which was in all probability at least partly due to the development of fatty acids. It seemed, therefore, possible that in the case of these milks, not only might the ozone have had a directly injurious action on the bacteria, but it might also have affected them indirectly by producing from the natural milk various bodies which might themselves also have to be considered as factors in the experiment. The milk in Flask 5 was in a late stage of decomposition and possessed of a most offensive odour; it was noticed that the offensiveness of this milk was considerably reduced after the passage of the ozone.

EXPERIMENT V.

Our next experiment was made in order to ascertain whether ozone had any influence on the virulence as apart from the mere vitality of bacillus tuberculosis and was carried out in the following way. Sputum rich in the specific bacillus was smeared over strips of filter-paper. These strips were then dried and afterwards exposed for varying periods to the action of highly-ozonised air. The exposure was insured by pinning out the strips on a board, which was hung about six feet from the same ozonising apparatus as that used in Experiment I. and in the same room. The apparatus was set at work two hours before the exposure of the sputum was commenced and was continued without intermission throughout the experiment. When the exposure was commenced the air of the room was so highly charged with ozone as to be extremely unpleasant and not respirable by anyone for more than a few minutes at a time. After undergoing exposures of the several durations given in the table below the strips of infected paper were moistened, stretched out on glass, and the surface which had been smeared with the sputum was scraped off lightly with the edge of a knife. The scraping from each strip was collected in a cubic centimetre of sterilised normal saline solution and doses of 0·2 cubic centimetre of the emulsions thus obtained were injected under the skin of the inguinal fold in guinea-pigs. As controls other guinea-pigs were similarly inoculated with some of the crude sputum and also with the scrapings from an infected strip of paper which had not been previously ozonised. 14 animals in all were inoculated; the following table gives their weights and the nature of the emulsion used for each:—

Animal.	Weight.	Inoculated with—
	Grms.	
Guinea-pig I.	500	Small quantity of crude sputum.
,, II.	470	,, ,, ,,

,, XIV.	370	,, ,, ,, ,, 8 ,,

The various animals were either allowed to die naturally or were killed with chloroform after definite signs of tuberculous infection had developed. And it may at once be said that a severe infection occurred in all the animals; there was not the least indication that the ozonisation had exerted any effect whatever on the virulence of the bacilli. As examples we may mention the following animals: guinea-pig I. died on the twentieth day after inoculation with a caseous abscess in the flank, infected mesenteric glands, and tubercles in the spleen; guinea-pig II. was killed on the twenty-second day after inoculation and was found to be in a similar condition; guinea-pig XI. died on the twenty-second and guinea-pig XIV. on the twenty-third day, both being again in a similar stage. The presence of the specific bacillus in one or other of the internal lesions was proved in the case of every animal on the list.

CONCLUSIONS.

Our experiments have made it clear that ozone in the dry state, and in such strength as we used it, has no appreciable action on the vitality of the various bacteria experimented with, and, so far, our results are in accordance with those of Sonntag and Ohlmüller. Nor did a prolonged exposure to the action of ozone diminish in any way the pathogenic virulence of bacillus tuberculosis in sputum as shown by Experiment V. Single experiments would also tend to show that ozone can have little, if any, effect on the pathogenic virulence of bacillus mallei and bacillus anthracis.

On the other hand, Experiment IV. would appear to confirm the conclusion arrived at by Ohlmüller as to the bactericidal property of ozone when passed through a fluid medium containing bacteria in suspension.

A comparison of the inactivity of ozone as a disinfectant in the dry state with its action in the presence of water suggests a superficial resemblance with other gases, such as chlorine and sulphur dioxide. In the absence of further experiment, however, it would not be possible to press the analogy too closely.

In the dry state, and under the conditions in which it occurs in nature, ozone, then, is not capable of any injurious action on bacteria so far as can be judged from our experiments; and we conclude that any purifying action which ozone may have in the economy of nature is due to the direct chemical oxidation of putrescible organic matter, and that it does not in any way hinder the action of bacteria, which latter are, indeed, in their own way working towards the same end as the ozone itself in resolving dead organic matter to simpler non-putrescible substances.

ON THE QUANTITATIVE ESTIMATION OF THE BACTERICIDAL POWER OF THE BLOOD

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

SECOND COMMUNICATION.[1]

IN a previous communication dealing with the quantitative determination of the bactericidal power of the blood I described the technique of a method by which the bactericidal power of blood could be determined. It will be remembered that for the purposes of the determination a measured volume of a series of graduated dilutions of serum were mixed in capillary cultivation-tubes, in each case with an equal volume of a liquefied gelatin culture containing in suspension an appropriate number of the species of micro-organism against which the blood was to be tested. Of the questions which arise in connexion with the above method two may be briefly dealt with here.

The first of these is the question as to whether in the case where no colonies develop in the mixture of serum and gelatin culture it may legitimately be inferred that a complete bactericidal effect has been achieved. This question can readily be determined by melting down the gelatin in the capillary cultivation-tubes and by blowing out their contents into a series of tubes of sterile nutrient broth. The results

[1] The first communication was published in THE LANCET of Dec. 1st, 1900, p. 1556.

that are obtained when this is done may be judged of by the observations set forth in the subjoined table (Table I.).

The second question relates to the influence exerted on the result of the quantitative estimation of the bactericidal power by the greater or smaller number of bacilli in the volume of culture brought in contact with the serum. The determination of this point manifestly involves on the one hand a determination of the number of bacteria present in the culture employed, and on the other hand a comparison of the effects of the serum when added to a series of graduated dilutions of the culture.

The method of carrying out the required operations rapidly and efficiently may be briefly described, more particularly as the technique in question enables us, as will be seen below, to arrive at a definite arithmetical expression for the bactericidal power which is exerted by a given blood upon a given bacterial culture.

A series of graduated dilutions of a broth culture of the required species of micro-organisms are first made. In the case of a culture of the typhoid bacillus it will suffice to employ, in addition to the undiluted culture, dilutions of 10, 100, 1000, 10,000, and 100,000. These dilutions can be made by using the graduated capillary pipette figured in my former communication. It will, however, be conducive to rapid work if a "mixing chamber" is formed upon the neck of the capillary pipette by heating and drawing it out a little beyond the capillary stem. When this has been done 10, 20, 30, or more volumes of fluid can be drawn up and mixed together without emptying the pipette. Given such a pipette, the stem of which has been divided into six equal divisions of 2·5 cubic millimetres, the procedure for making a convenient quantity, say 30 volumes (0·75 cubic centimetre), of a tenfold, or any further tenfold multiple, of the bacterial culture would be as follows. Six volumes of sterile broth are first filled into the capillary stem; a bubble of air is then taken in; and, while the first six volumes of broth are passing up into the mixing chamber, another six volumes of broth; and so on in series until in all 27 volumes of broth and a final bubble of air have been taken in. Three volumes of the broth culture are now introduced into the stem of the capillary pipette. The whole contents are thoroughly mixed in the mixing chamber and are then expelled into a sterile and covered watch-glass.[2] After the pipette has been thoroughly washed

[2] The sterile watch-glasses required can be most expeditiously prepared by heating them on wire gauze until a red pencil mark placed on each with one of the pencils sold for writing on glass begins to blacken. The temperature indicated by the blackening of such red pencil marks is well over 200° C.

TABLE II.

Source of blood and nature of the bacterial culture against which it was tested.	Determination of the number of bacteria in the culture.		Result of the enumeration of bacteria in the original culture.	Determination of the bactericidal power of the serum.		Bactericidal power of the blood as estimated from the foregoing.
	Dilutions of the culture and volume of these dilutions employed for the bacterial enumeration.	Number of colonies which developed from the specified volume of diluted culture.		Dilutions of the bacterial culture which were mixed in equal volume with undiluted serum.	Result of the cultivation when the mixtures particularised in the last column were after 24 hours planted out on nutrient agar or broth.	
Blood of A. E. W. tested against an 18-hour peptone and salt cultivation of the cholera vibrio.	5 c.mm. of a 1 in 100,000 dilution. Blood of A. E. W. tested against the culture as above ...	As above.	As above.	As above.	Undiluted. 10-fold dilution. 100- ,, ,, 1,000- ,, ,, 10,000- ,, ,, 100,000- ,, ,,	Numerous colonies on agar. Three colonies ,, ,, No growth. ,, ,, ,,	1 c.mm of serum kills nearly 136,000 of the typhoid bacilli employed.
Blood of A. E. W. tested against a 48-hour old broth cultivation of staphylococcus albus	Tubes 1 and 2, 5 c.mm. of a 1 in 10,000 dilution. Tubes 3 and 4, 5 c.mm. of a 1 in 100,000 dilution. Tubes 5 and 6, 5 c.mm. of a 1 in 1,000,000 dilution.	Tubes 1—12 ,, 2— 6 ,, 3— 1 ,, 4— 1 ,, 5— 0 ,, 6— 0 Average in 5 c.mm. = 0·95.	1 c.mm. of the culture contains 19,000	Undiluted. 10-fold dilution. 100- ,, ,, 1,000- ,, ,, 10,000- ,, ,, 100,000- ,, ,, 1,000,000- ,, ,,	Growth on agar. ,, ,, ,, ,, ,, ,, ,, ,, ,, ,,	* 1 c.mm. of serum fails to kill 0·2 of the staphylococci employed.

* With a view to determining whether, in default of a definite bactericidal effect, an inhibitory effect was exerted by this serum on the growth of the staphylococcus a determination of the anti-bacterial power was made also by the gelatin method described in my previous communication. This determination, in addition to resolving the particular point referred to, yielded results which are of interest here as establishing the substantial accuracy of method of enumeration employed above. The details of the procedure and the results obtained were briefly as follows. Five cubic millimetres of the undiluted staphylococcus culture were placed in 16 cubic centimetres of liquefied sterile nutrient gelatin and were thoroughly mixed. *This gelatin thus represented a 3200- (200 × 16) fold dilution of the original broth culture of staphylococcus.* From this gelatin four serum and four control tubes were filled in as follows:—

Serum Tubes.

—	Filled in with—	Number of colonies which developed.
No. 1	2·5 c.mm. of gelatin culture + 2·5 c.mm. of serum.	0
No. 2	2·5 c.mm. of gelatin culture + 2·5 c.mm. of serum.	0
No. 3	2·5 c.mm. of gelatin culture + 2·5 c.mm. of serum.	0
No. 4	2·5 c.mm. of gelatin culture + 2·5 c.mm. of serum.	0

Control Tubes.

—	Filled in with—	Number of colonies which developed.
No. 1	2·5 c.mm. of gelatin culture + 2·5 c.mm. sterile broth.	7
No. 2	2·5 c.mm. of gelatin culture + 2·5 c.mm. sterile broth.	14
No. 3	5 c.mm. of gelatin culture + 5 c.mm. sterile broth.	26
No. 4	5 c.mm. of gelatin culture + 5 c.mm. sterile broth.	24

Average of all the controls, 11·5 in 2·5 c.mm., 4·6 in one c.mm., of the gelatin.
Average (omitting from consideration control No. 1), 13·0 in 2·5 c.mm., 5·2 in one c.mm., of the gelatin.
Multiplying by 3200, the factor corresponding to the dilution of the original culture in the gelatin, we arrive at the figures of 14,700 and 16,640 respectively for the number of staphylococci in the original culture. The latter figure in particular is in fairly satisfactory agreement with the result of the enumeration as set forth in the table.

out in boiling sterile water the same procedure is repeated in the case of each further dilution with the difference that the last three volumes are filled in, instead of with the undiluted culture, with the previous dilution of that culture.

Having in this way obtained the required dilutions the enumeration of the number of bacteria contained in the last dilution—or, if desired, in the last two dilutions—would be taken in hand. For this purpose one volume of the dilution or dilutions in question are introduced along with one volume of liquefied, sterile nutrient gelatin into a "capillary cultivation-tube." This is done by the methods already described in my former communication. With a view to checking the accuracy of the work such tubes are in each case filled in in duplicate and triplicate. By enumeration under the microscope of the number of colonies, developing in the tubes thus filled in, the number of bacteria in the measure (2·5 or 5 cubic millimetres) of diluted culture is elicited. From this by a simple arithmetical calculation the number of bacteria in the unit measure of undiluted culture is obtained.

After the completion of the procedures which subserve the purpose of the bacterial enumeration, those directed to the determination of the bactericidal effect of the blood on the various dilutions of the bacterial culture are taken in hand. For this purpose a series of sedimentation-tubes, such as those figured by me in THE LANCET of March 6th, 1897, p. 657, are taken in hand, after they have been plugged with cotton-wool and sterilised in the flame. Into each of these is introduced one volume of undiluted serum and one volume of typhoid culture, the successive tubes being of course filled in with the successive dilutions of the culture. Mixture of the contents is then effected in the mixing chamber, and the tube is sealed after the mixture has been driven down for a moment to the point of the stem, so as to secure that any bacteria which have been left there shall be brought into contact with the serum. The sealed tubes are then incubated at 37° C. for from 18 to 24 hours. After this they are blown out with aseptic precautions either into nutrient broth or upon the surface of an agar plate.[3] The results obtained in a series of successive estimations made by this method are as follows (Table II.).

The conclusions which can be gathered from the results set forth in the tabular statement above may be summarised as follows:—

1. What is measured by the gelatin method described in my former communication is rather the total *anti-bacterial power* of the blood than the bactericidal power proper. To determine how much of the result which is registered is referable to an inhibition of the growth of the bacteria, and how much to a direct bactericidal action, it is necessary, after the cultivation-tubes have been incubated and examined microscopically, to melt down the gelatin and to blow out the contents of the tubes into sterile nutrient broth.

2. Where it is desired separately to estimate the *bactericidal power* this can readily be done by making a series of graduated dilutions of a bacterial cultivation in broth, and by mixing, in the manner described in the present communication, one volume of each of these with one volume of undiluted—or, if necessity should arise, diluted—serum. This method may appropriately be applied when we are dealing with bacteria such as the vibrio of cholera or the typhoid and diphtheria bacillus, which are readily killed off by the normal human blood.

3. When the method last in question is employed, and when the bacteria in the culture employed have been enumerated in the manner indicated, a convenient arithmetical expression for the bactericidal power is obtained by specifying the number of micro-organisms which one cubic millimetre of serum is capable of killing.

4. Where (as in the case of the staphylococcus and apparently, also, in the case of the streptococcus and bacillus of plague) we have to deal with bacteria which are not killed off, or which are killed off only in small numbers, by the normal human blood, or, again, where we are dealing with conditions (such as those frequently met with in persons recently convalescent from typhoid fever) when the blood has lost much of its normal bactericidal power, the gelatin method, measuring as it does the combined inhibitory and bactericidal power, may appropriately come into application.

Netley.

[3] The difficulties incident to the swamping of the agar-plate by water of condensation can, in conformity with a suggestion which I owe to Major W. B. Leishman, R.A.M.C., be avoided by fastening a pledget of absorbent cotton-wool down with gum on to the lower surface of the lid of the Petri's dish.

RESULT OF MAJOR AMPUTATIONS

TREATED ANTISEPTICALLY IN THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE, DURING THE YEAR 1899, AND FOR A PERIOD OF TWENTY-ONE YEARS AND NINE MONTHS—VIZ., FROM APRIL 1ST, 1878, TO DEC. 31ST, 1899, INCLUSIVE.

BY H. BRUNTON ANGUS, M.B., M.S. DURH., M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

MR. F. PAGE has asked me to carry on the record of major amputations performed in the Royal Infirmary, Newcastle-upon-Tyne.[1]

TABLE I.—*Table of Major Amputations treated Antiseptically in the Royal Infirmary, Newcastle-upon-Tyne, during the Year 1899.*

—	Injury.			Disease.			Total.
	No.	Recovered.	Died.	No.	Recovered.	Died.	
Double amputations	3	2	1	—	—	—	3
Hip-joint	—	—	—	—	—	—	—
Thigh...	5	4	1	16	14	2	21
Knee-joint	3	3	—	2	2	—	5
Leg	7	6	1	6	6	—	13
Ankle-joint	3	3	—	7	7	—	10
Shoulder-joint ...	—	—	—	—	—	—	—
Arm	3	3	—	3	3	—	6
Forearm	7	6	1	1	1	—	8
Wrist...	1	1	—	—	—	—	1
—	32	28	4	35	33	2	67

During the year 1899 67 major amputations—three of which were double amputations—were performed on 64 patients, six of whom died and 58 recovered. The mortality was, therefore, at the rate of 9·3 per cent. Of the 32 cases of amputation for injury four patients died, or a mortality of 12·5 per cent. There were 25 cases of primary amputation and four deaths—a mortality of 16 per cent. 35 of the amputations were for disease and in two cases the patients died—a mortality of 5·7 per cent. In one of the double amputations the amputations were primary in the legs; unfortunately both stumps had to be re-amputated owing to sloughing of the flaps. The patient nevertheless made a good recovery.

PRECISE CAUSE OF DEATH AFTER AMPUTATION FOR INJURY.

1. *Double amputation.*—A man, aged 46 years, was knocked down by a train and sustained such injuries that a double amputation was performed in the right leg by Teale's amputation, and on the left side amputation through the lower third of the thigh. He died 77 hours after from acute spreading gangrene of the right leg. The bacilli of malignant œdema were found in the discharge of the stump and surrounding tissues. There was an abrasion of the skin of the flaps, and it was thought that the bacilli had entered there in spite of thorough cleansing. As soil and dirt were ground into the legs it was suggested that the bacilli were already in the lymphatics at the time of the operation. The operation was performed six hours after the accident.

2. *Thigh.*—A man, aged 45 years, died three days after amputation of the thigh performed for a crushed leg from shock.

[1] THE LANCET, March 21st, 1896, p. 763.

3. *Leg.*—A man, aged 22 years, died 14 hours after an amputation of the leg just above the ankle. He was knocked down by an engine and in addition had a lacerated thigh and a fractured pelvis. He was infused with four pints of normal saline solution.

4. *Forearm.*—A man, aged 78 years, was knocked down by a cab on July 26th, 1899. He had a scalp wound, was concussed and lost a lot of blood from his hand being nearly severed. Amputation in the middle of the forearm was performed. The wound healed, but he gradually became exhausted and died on August 5th, never having properly shaken off the effects of the shock.

PRECISE CAUSE OF DEATH AFTER AMPUTATION FOR DISEASE.

1. *Thigh.*—A man, aged 39 years, had a sarcoma of the thigh. Amputation was performed on March 28th; the femoral glands were affected and it was necessary to tie the femoral artery and vein at Poupart's ligament, as they were involved. The flaps became gangrenous; septicæmia followed and he died on March 31st.

2. *Thigh.*—A man, aged 56 years, had his thigh amputated for senile gangrene of the foot. The operation was done on July 11th and he died on the 14th from exhaustion.

TABLE II.—*Result of Major Amputations treated Antiseptically in the Royal Infirmary, Newcastle-upon-Tyne, from April 1st, 1878, to Dec. 1st, 1899—a Period of 21 Years and Nine Months.*

—	Injury.			Disease.			Total.
	No.	Recovered.	Died	No.	Recovered.	Died.	
Double amputations	27	14	13	—	—	—	27
Hip-joint	8	3	5	36	22	14	44
Thigh	100	77	23	280	260	20	380
Knee-joint	13	12	1	10	8	2	23
Leg	135	119	16	130	127	3	265
Ankle-joint	51	50	1	175	173	2	226
Shoulder-joint	28	26	2	19	18	1	47
Arm	70	63	7	37	36	1	107
Forearm	68	65	3	38	38	—	106
Wrist	8	8	—	—	—	—	8
—	508	437	71	725	682	43	1233

In the above record 1233 major amputations have been performed in the Royal Infirmary, Newcastle-upon-Tyne. Of this number 1119 patients have recovered and 114 have died—a mortality of 9·2 per cent. 508 cases were those of amputation for injury and 71 patients died—a mortality of 13·9 per cent.; 725 were for disease and 43 patients died—a mortality of 5·9 per cent.

Newcastle-on-Tyne.

A METHOD OF

DISTINGUISHING BACILLUS COLI COMMUNIS FROM BACILLUS TYPHOSUS BY THE USE OF NEUTRAL RED.

BY WILLIAM HUNTER, M.B., C.M. ABERD.,
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL.

(*From the Bacteriological Laboratory, London Hospital, E.*)

THE question of the relationships between the bacillus typhosus and the bacillus coli communis has played an important part in the bacteriological investigation of cases of enteric fever. Since Eberth, Gaffky, and Koch published their papers on the constant presence in the intestine, spleen, and other organs of a characteristic bacillus in cases of typhoid fever, there has been much controversy as to whether this bacillus—the bacillus typhosus—is merely a variety of the bacillus coli communis. Although the majority of bacteriologists are of opinion that these micro-organisms are specifically different, so eminent an investigator as Gabriel Roux has all along maintained that the physiological tests which are utilised for the differentiation of the two micro-organisms are insufficient to establish a specific difference between them. As Lehmann and Neumann [1] remark, it is quite possible that the bacillus typhosus may only be a variety of bacillus coli communis—a variety which has lost certain zymogenic but gained certain pathogenic characters.

Considerable attention has been paid to the biological characters of the two organisms in order to distinguish the one from the other. Although many tests—as the indol reaction, the milk test, the reaction with glucose litmus agar, &c.—have been extensively used in order to diagnose between them it is found by repeated examination of different strains of these microorganisms that there is scarcely one of the many tests which may not fail. Many investigators have repeatedly demonstrated that bacillus coli communis may, under certain circumstances, lose even its power of producing indol and of coagulating milk. For instance, Lembke [2] has found that certain strains of bacillus coli communis fail to produce gas in media containing glucose; Scheffler [3] found that the production of acid may fail, and according to Lehmann and Neumann the bacillus typhosus may occasionally, though rarely, grow atypically upon potato, the growth resembling bacillus coli communis.

Even the agglutination test in distinguishing bacillus typhosus from bacillus coli communis is *not always reliable.* From the researches of Pfeiffer and others it was thought that this agglutination reaction would afford an absolutely reliable method of distinguishing these two micro-organisms from each other and from other micro-organisms belonging to the typhoid group. The recent researches of Mann,[4] Vedel,[5] Kohler and Scheffler,[6] and others, however, have shown that some races of the bacillus coli communis give a positive reaction even in high degrees of dilution with typhoid serum. In this connexion it is important to remember that sera obtained from patients suffering from enteric fever are in the majority of instances capable of agglutinating the bacillus coli communis as well as the bacillus typhosus. This, as Stern,[7] Biberstein,[8] Widal,[9] and others have shown, is due to mixed infection, one of the commonest occurrences in cases of enteric fever. An excellent example of this fact was published by Widal in 1897. The blood serum obtained from a convalescent typhoid fever patient agglutinated a strain of bacillus typhosus in the dilution of 1 in 20. A paracolon bacillus which he had isolated from an abscess of the thyroid gland, however, was agglutinated by this serum in the dilution of 1 in 12,000. Eight days later the agglutination reaction with the bacillus typhosus had disappeared, the paracolon bacillus, however, still giving the reaction in the dilution of 1 in 12,000. During the course of the disease the blood serum of this patient gave constantly an agglutination reaction with bacillus typhosus in the dilution of 1 in 100. That this case was one of secondary infection with bacillus coli communis is clear, and, as Widal concluded, the blood serum of the patient gave two distinct and independent reactions. The only sera, therefore, which can be employed for differential diagnosis are those obtained from animals immunised against the bacillus typhosus *in pure culture.* The maintaining of the bacillus typhosus in pure culture and at a constant degree of virulence during the process of immunisation, however, is a most difficult technical procedure. Unless excessive care is taken during the process of increasing the virulence of the bacillus typhosus contamination with bacillus coli communis will take place. If such cultures be employed for purposes of immunisation then coli agglutinating substances will also be present in the blood serum of the animal immunised. Therefore, so great difficulties being present the test cannot be regarded, as it is by some, as final. All that can be said at present is that given a suspected bacillus typhosus culture a negative result is of greater value than a positive reaction obtained with a suspected bacillus coli culture. At the present time, therefore, we possess no single test which can be considered crucial. Before coming to any definite conclusion each test

has to be extremely carefully performed and taken in conjunction with the others. By such means only is it possible to distinguish the one micro-organism from the other.

Recently a good deal of attention has been directed to the use of coloured media as a means of diagnosing between morphologically and biologically related micro-organisms. Many of the methods proposed have been highly satisfactory, this being due mainly to the fact that the slightest change in the medium used is easily recognisable.

The first employment of colouring matter as a means of diagnosis between closely related micro-organisms was proposed by Neeggerath.[10] Shortly after other colour tests were proposed by Cahen,[11] Buchner,[12] Spina,[13] Kitasato and Weyl.[14] In order to distinguish bacillus typhosus from bacillus coli communis Wuntz[15] recommended the employment of a solid medium to which was added lactose and litmus. The further development of our knowledge in regard to the biological properties of these micro organisms soon showed that such a medium would not afford a reliable method of diagnosis. More recently a large number of colour tests have been recommended, the most important of these being the use of fuchsin agar, recommended by Gasser[16]; fuchsin and malachite green by Marpmann[17]; acid gelatin with methyl green by Uffelmann[18]; and a medium composed of lactose, urea, and litmus by Kashida.[19]

The great drawback to all these colour methods of diagnosis is that they do not afford any opportunity of *rapid* diagnosis. The majority have as their main constituent, gelatin, a substance upon which the bacillus typhosus and the bacillus coli communis grow relatively slowly. Therefore, as it is usually important to be able to give a rapid diagnosis as to the presence or absence of these micro-organisms it is obvious that the use of media containing gelatin must be avoided.

In 1898 Rothberger[20] published a series of results dealing with the action of a number of bacteria on various aniline colours. His results are specially interesting as he found that by the use of neutral red or saffranin, he had a valuable diagnostic method of distinguishing bacillus typhosus from bacillus coli communis. The method which he employed was agar-agar to which was added a small quantity of a concentrated watery and sterilised solution of neutral red or saffranin. The tubes containing this neutral red or suffranin agar were inoculated with bacillus typhosus and bacillus coli communis and incubated at 37° C. for 24 hours. According to Rothberger, the following result is obtained in the tubes which have been inoculated with bacillus coli communis. The neutral red agar becomes greenish yellow and markedly fluorescent. The saffranin agar becomes completely decolourised. In the tubes which have been inoculated with bacillus typhosus no perceptible change is produced in either of the media.

This result is very striking. From the further researches of Rothberger and the more or less confirmatory work of Scheffler,[21] the test appears to give constant results. During the past 18 months I have had frequent opportunity of studying the morphological and biological characteristics of the bacillus typhosus and bacillus coli communis, and from the results obtained I came to the conclusion that in a few cases it was scarcely possible to establish with absolute certainty the presence in pure culture of bacillus typhosus or bacillus coli communis. The publication by Rothberger of the results which he had obtained with neutral red appeared to me to be worthy of further study and the following are briefly the methods which I have employed and a summary of the results obtained. In order to determine the exact nature of the reaction the method which I adopted is as follows. To a number of tubes, each containing approximately 10 cubic centimetres of ordinary peptone agar, I added from 0·1 to 0·5 cubic centimetre of a concentrated watery solution of neutral red. The agar was then melted and the colouring matter evenly distributed throughout the medium. The tubes on being cooled down to about 42° C. were inoculated with one oese of a pure culture in bouillon of bacillus coli communis, and after thorough shaking incubated at 37°C. Control tubes with bacillus typhosus were prepared in exactly the same way. After 24 hours the tubes which had been inoculated with bacillus coli communis showed an abundant growth with marked gas production. The medium, instead of being of a deep red colour, had assumed a superb canary-yellow fluorescent tint. The fluorescence was most marked in the deeper parts of the tube. Further, slight liquefaction of the agar had taken place. The typhoid tubes, on the other hand, showed absolutely no change, although a good growth was obtained. After 48 hours the coli tubes were more or less completely decolourised and the fluorescence was decidedly less marked. The typhoid tubes still showed no change. This remarkable result having been obtained further experiments were made in order to determine as exactly as possible the most favourable conditions under which the method succeeds.

If plate cultivations of bacillus typhosus and bacillus coli communis be made with neutral red agar a somewhat surprising result is obtained. After 24 hours' incubation of the plates a marked decolourisation of the medium takes place. This change is as well marked in the typhoid as in the coli plates. Further, the medium is usually found to contain a large number of needle and star-shaped crystals of a reddish colour—probably crystals of neutral red or some product from it. On more minute examination of the plates the colonies of both micro-organisms appear to have taken up a great deal of the colouring matter. The centre of each colony is constantly found stained of a deep red colour. After incubation of the plates for a few days the medium as well as the colonies of both micro-organisms becomes completely decolourised. No fluorescence is ever observed. The red crystals already mentioned remain unchanged. I have obtained similar results in plate cultures prepared with glycerine agar and peptone gelatin. Somewhat similar results have been obtained by Rothberger, who rightly concludes that this method of procedure is of no value. The only point of interest attached to this result is that it clearly proves that the bacillus typhosus is quite as capable as the bacillus coli communis of decolourising neutral red in plate cultures.

By far the most satisfactory results are obtained with shake or stab cultures. Ordinary agar gives usually good results, but glucose agar is to be preferred. My results agree with those obtained by Scheffler that the quickest and most constant results are obtained with glucose agar. Usually some idea as to the presence or absence of bacillus coli communis can be obtained in from 12 to 24 hours. There appears to be some difference of opinion as to the amount of glucose required. According to Scheffler 0·3 per cent. glucose gives the best results. My experience leads me to believe that the development of the fluorescence depends to a great extent upon the amount of glucose present. If present in small quantity, a marked fluorescence is developed after 24 hours; if, on the other hand, glucose be present in the amount of from 1·5 per cent. to 2 per cent., little of this fluorescent appearance is met with, the majority of the tubes being of a uniform yellow colour. In my opinion too great stress is laid upon the occurrence of fluorescence by Scheffler, the change in colour from red to yellow in from 12 to 24 hours being a sufficient guarantee of the presence of bacillus coli communis. As already mentioned, gelatin cannot be used. The reaction, however, although slow in appearance, occurs equally well, the fluorescence and yellow colour being in some cases markedly developed. Here, again, glucose gelatin gives the most satisfactory results. Upon bouillon the reaction also succeeds. On this medium the fluorescence is only faintly developed. After 24 hours the broth is usually of a uniform yellow colour. Similar results have been obtained with liquid blood serum, peptone water, milk, &c. A point of great interest in connexion with the occurrence of the reaction upon different media is the negative result obtained by the use of a proteid free medium. If neutral red be added to Uschinsky's medium which is then inoculated with bacillus coli communis absolutely no change in colour is produced, although a good growth is obtained.

Since commencing my experiments with neutral red I have tested a number of strains of bacillus coli communis and bacillus typhosus, and under the conditions specified I have obtained absolutely constant results. Bacillus coli communis always produces a fluorescence and change of colour in the neutral red media in 24 hours, bacillus typhosus never.

Through the kindness of Mr. W. C. C. Pakes of Guy's Hospital I have had the opportunity of submitting to this neutral red test a culture of the so-called bacillus enteritidis of Gaertner. In all of the tubes inoculated with this bacillus a marked reduction of the neutral red took place in less than 24 hours. The reaction was indistinguishable from that obtained with typical coli cultures. This result is extremely important, as it brings forward additional proof that the bacillus enteritidis is merely a variety of bacillus coli communis as suggested by Lehmann and Neumann. The majority of cultures of micro-organisms, as staphylococcus, streptococcus, pneumococcus, bacillus diphtheriæ, bacillus mallei, bacillus anthracis, bacillus pyocyaneus, and vibrio choleræ, &c., which I have had at my disposal have been submitted to this test, but *in no case* has the slightest reduction taken place. At the same time the reaction cannot be regarded as specific. As found by Rothberger bacillus tetani, bacillus œdematis maligni, and the bacillus Chauvæ also give the reaction. As these micro-organisms, however, possess so many definite points of distinction of their own this can scarcely affect the value of the reaction in regard to bacillus coli communis. Further, Scheffler has obtained the reaction with a number of micro-organisms isolated from water and fæces. Probably these belong either to the coli group, which is extremely large, or to the already mentioned anaerobic forms.

The reaction must be regarded as a process of reduction as suggested by Rothberger and conclusively proved by Rambouséek.[22] Neutral red is an extremely irreducible substance. It is only when nascent hydrogen has acted on a solution for some time that the characteristic fluorescence and yellow colour are produced. This being so, it is easy to understand why the bacillus typhosus fails entirely to effect the slightest change in colour in the neutral red, the powers of reduction of the bacillus typhosus being extremely slight. The members of the coli group, on the other hand, are well known as powerful reducing agents.

Conclusions.—1. That bacillus coli communis possesses to a marked degree the power of reducing neutral red, producing a superb canary yellow fluorescent colour of the medium. 2. That the so-called bacillus enteritidis of Gaertner also produces this reaction, and is probably only a variety of bacillus coli communis. 3. That the bacillus typhosus never possesses this power of reduction. 4. That the common pathogenic micro-organisms do not give this reaction. 5. That by means of neutral red it is possible within from 12 to 24 hours to diagnose with absolute accuracy the presence of bacillus coli communis. Finally, as far as my experience goes, it is possible to diagnose by means of neutral red the true coli group from the typhoid group of micro-organisms.

NOTE ON A CASE OF INFLUENZA WITH MENINGITIS AS A COMPLICATION.

BY ARTHUR FOSTER, M.D., C.M. EDIN.

A WOMAN, aged 54 years, the mother of two children, was in perfect health up to Jan. 28th, 1901. On awakening on the morning of the 29th she was suffering from pains in the back and legs, with a sore-throat and headache. She did not remain in bed, however, but endeavoured to follow her occupation, with the result that during the afternoon she had to relinquish it, the pain in the back having become very acute. The following morning (the 30th) I saw her for the first time. She then complained of intense pain in the lumbar region, aching pains in the legs and shoulders, a sore-throat, and some headache. There had been no delirium and she talked quite rationally. On examination slight tonsillitis was to be seen; the tongue was thickly coated with a white fur, the bowels were constipated, the lungs were healthy, the urine was free from albumin, the temperature was 103·5° F., the pulse was 95 per minute, and the respirations were 25 per minute. She was given a mixture containing tincture of nux vomica and salicylate of soda. On the 31st she was in much the same condition, though the pain in the back was rather better. The next morning (Feb. 1st) the headache was more severe and there was nausea, which during the day developed into attacks of vomiting and for which the usual remedies were of no avail. The temperature was now 104°, the pulse was 90, and the respirations were 36. At 6 P.M. of the same day the temperature quickly dropped to 97° (taken in the mouth), the pulse was regular (72), and the respirations were 26. She now began to have difficulty in speaking and swallowing and became drowsy. During the night the temperature gradually rose again and on the morning of the 2nd it had reached 103·5° with a pulse of moderate tension at 72 and a respiration, accompanied by puffing out of the lips, of 50. She was quite unable to talk or to swallow, had troublesome attacks of hiccough, and was in a state of stupor. Rigidity in the muscles of the neck and retraction of the head now became very marked, strabismus appeared, muscular tremors were to be felt and seen in the face, arms, and legs, there was partial paralysis of the muscles of one side of the face, and the urine was passed unconsciously. It was clearly evident that a severe case of meningitis had to be dealt with and icebags were freely applied to the head. On the morning of the 3rd the temperature was 101·5°, the pulse was 70, and the respirations were 72. The patient was now comatose and could not be roused. In the evening of the same day the action of the heart, which had previously been quiet, became so tumultuous that it shook the bed and during the night the temperature fell below normal and she passed quietly away.

There does not appear to be any doubt as to the diagnosis of influenza, though at first the acute pain in the back suggested small-pox, which the subsequent events disproved. Moreover, the son, who resided with his mother, was at the same time passing through a mild attack of influenza.

Deaths from meningitis supervening on influenza would appear to be rare, though Althaus[1] considers it a frequent complication. Two forms of it are described: 1. That in which there is a simple benign lesion, seldom fatal and which according to Maxime[2] is due to the special action of the toxins secreted by the influenzal microbes, producing inhibition phenomena, toxins which appear to have a predilection for the nerve-centres and for which the cerebro-spinal fluid serves as a receptacle. Althaus[3] in a series of post-mortem examinations has also noted this predilection for the nerve-centres, having found intense hyperæmia in the pia mater and brain, particularly at the base of the brain. 2. That in which the lesion is more severe, generally fatal, and in which the streptococcus, staphylococcus, or other bacilli play an important part. Cases of this kind have been described by Bristowe,[4] Nicolson,[5] and Judson Bury.[6] No necropsy was obtainable in the above recorded case and it is impossible to be sure as to what was the exact nature of the meningitis. There was certainly no history of ear disease or other septic trouble. Perhaps it may be of interest to note that for some weeks previously to her illness she had been worried and had suffered much mentally by family troubles.

THREE CASES OF CERVICAL SPINA BIFIDA TREATED AS OUT-PATIENTS BY OPEN OPERATION.

BY JAMES H. NICOLL, M.B. GLASG.,

CONSULTING SURGEON TO THE EAR HOSPITAL, EXTRA SURGEON TO THE CHILDREN'S HOSPITAL, ASSISTANT SURGEON TO THE WESTERN INFIRMARY, AND CONSULTING SURGEON TO THE LUNACY BOARD, ETC., GLASGOW.

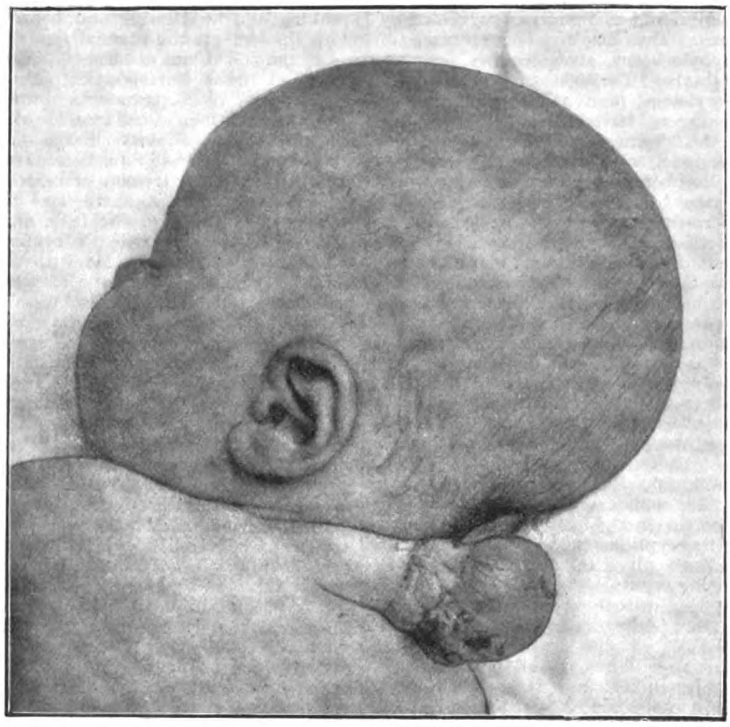
CASE 1.—The patient came to the Glasgow Children's Hospital, at the age of seven weeks, on June 15th, 1900. Fig. 1 is a reproduction of a photograph taken on that date. Pinching of the neck of the sac between the finger and thumb produced smart jerking upward of the lower limbs after the manner of the wooden figure toy on pulling the string. On June 19th, chloroform being administered by the house surgeon, Dr. J. R. Chalmers, the tumour was removed.

There was nothing special to note in the operation except that the cord took a geniculate curve into the neck of the sac, to cover which the lateral flaps had to be made longer than usual. The child was sent home after operation and was nursed by the mother under the directions of one of the sisters. The wound healed by first intention and the sutures were removed on the seventh day.

CASE 2.—The patient came to the Children's Hospital Dispensary in the end of July, 1900, at the age of two months. Fig. 2 is a reproduction of a photograph taken at that time.

CASE 3.—This patient, who came the same week as the patient in Case 2, was aged five months. A photograph was taken at that time. Unfortunately, it was taken on a plate which had just been used for a case of talipes and so was spoiled.

FIG. 1.



Cervical spina bifida. Meningocele into the neck or peduncle of which the spinal cord bulges in the form of a loop. Photograph taken four days previous to operation.

FIG. 2.

Cervical spina bifida. Pure meningocele. Photograph taken a week before operation.

Both cases were operated on on August 7th, 1900. Chloroform was administered by the house surgeon, Dr. Chalmers. Both proved to be pure meningoceles and the operations offered no points of special interest. The children were sent home after operation and were nursed by their mothers under the directions of one of the sisters. Both healed by first intention, the sutures being removed on the seventh day.

Fig. 3 is a reproduction of a photograph of the patients taken in the early part of October. At that time they were all well, as they are now. They were shown to the Glasgow Medico-Chirurgical Society at a meeting on Nov. 2nd, 1900.

FIG. 3.

CASE 2. CASE 1. CASE 3.

Photograph of the three cases of cervical spina bifida after excision of the sacs. The patients at this date are aged four months, seven months, and seven months respectively. Operation—Case 1 three and a half months, and Case 2 and Case 3 two months previously.

Remarks.—Spina bifida is not uncommon in the cervical region (though, of course, comparatively much less frequent than in the lumbar region). I have operated on a number of cervical cases, one of which, operated on at the Children's Dispensary in 1896, was, like the three foregoing cases, successfully treated as an out-patient, the child being nursed by the mother under the directions of one of the sisters.

Of all cases of spina bifida, those of the cervical region are the best suited for post-operative treatment as out-patients. I have, however, treated cases of the affection in the lumbar region as out-patients after operation and have shown such cases to various medical societies. With properly selected cases I have found the results satisfactory. To insure success selection is less concerned with the infant than with the mother and her circumstances. Given a tiny infant the chances of success in the mother's care, provided she is intelligent and can devote the first few days entirely to nursing under specific instructions, are quite as good as in the wards of an average hospital. The ideal conditions such as may be obtained in private cases include nursing by the mother and by two nurses in addition.

It is not necessary here to detail the steps of the operation carried out in these three cases. Full accounts of the different methods which I have followed in cases of spina bifida and in cases of hydrocephalus may be found in a paper on the subject in the Glasgow Hospital Reports (vol. ii., 1900), and in an earlier paper read at the meeting of the British Medical Association in Edinburgh and published in the *British Medical Journal* (Oct. 15th, 1898) and *Pædiatrics* (1899).

Glasgow.

A CASE OF FRACTURE OF THE STERNUM.

BY J. SACKVILLE MARTIN, M.D. EDIN., M.R.C.S. ENG.

A SHORT note on this uncommon variety of fracture may be of interest to readers of THE LANCET.

A man, aged 23 years, was working in the pit on Dec. 5th, 1900. He was leaning forwards, his body bent at right angles to the legs, when a truck which was passing crushed him against a "stack" or upright piece of wood used in keeping up the roof of the gallery. The direction of the force applied was laterally from shoulder to shoulder, and from the fact that his position caused the shoulder to drop forwards the force would naturally act anteriorly to the mid-axillary line. He complained principally of stiffness and soreness about the shoulder-joint and this led me at the time to overlook the condition of the sternum. Five days afterwards, however, I found a very definite projection over the left side of the manubrium sterni running vertically downwards. The stiffness of the shoulder had passed off, but any movement which involved bringing the left arm forwards caused pain. On pressing with one finger on the projection and the other on the first rib, crepitus could be elicited. I was inclined to diagnose fracture of the sternum, but being aware of its rarity, hesitated to do so without a further opinion. Mr. J. E. Platt, surgeon to the Manchester Royal Infirmary, to whom I sent the patient, confirmed the diagnosis and very kindly wrote to me stating that, in his opinion, the fracture started at the supra-sternal notch and ran downwards and to the left, reaching the edge of the manubrium below the attachment of the first costal cartilage. The detached fragment was somewhat displaced forwards. He also had a skiagram taken, unfortunately with a negative result.

Fractures of the sternum are rare and the form usually described in text-books is a transverse one caused by a heavy weight forcibly flexing the spine and doubling the trunk upon itself. In this case we have a crushing force acting laterally upon the sternum through the line of both clavicles. The clavicles form with the manubrium sterni an arc, and opposing forces applied to both extremities would tend to approximate them and to throw a strain on the centre of the arc. The sudden direct impact of the force through the clavicles combined with this approximation of the arc's extremities probably caused the fracture and would account for the forward displacement of the loose fragment. It is a matter for surprise that the clavicles should have remained uninjured. A fracture of the clavicle, or even a dislocation at the sterno-clavicular joint, would have been a more common result of such an injury.

It is of interest to note the small amount of disability caused by the fracture. The patient could perform any movements of the left arm five days after the accident and only those associated with the action of the pectoralis major caused him pain. The only treatment adopted was to keep the left arm in a sling, and on Jan 22nd the fracture

had quite healed and the arm could be used freely without causing him pain. There is, however, a definite ridge, the result of the deformity produced by the displacement of the fracture. I am indebted to Mr Platt for permission to make use of the information he so kindly gave me.

Leigh, Lancashire.

A CASE OF CEREBRO-SPINAL MENINGITIS.

BY FRANCIS RILEY, M.B., B.S. LOND., F.R.C.S. ENG.

IN view of the rarity of sporadic cases of this disease in England it is of some importance that individual cases should be put on record, and the following case presents several points of interest.

A girl, aged five years, who had previously been in good health except that she had been noticed to be lethargic in the mornings, was suddenly attacked with headache and vomiting followed by convulsions. No cause could be assigned except that she had knocked her head against the bedpost in the morning. The same evening the temperature was 103·5° F., and as it remained about the same

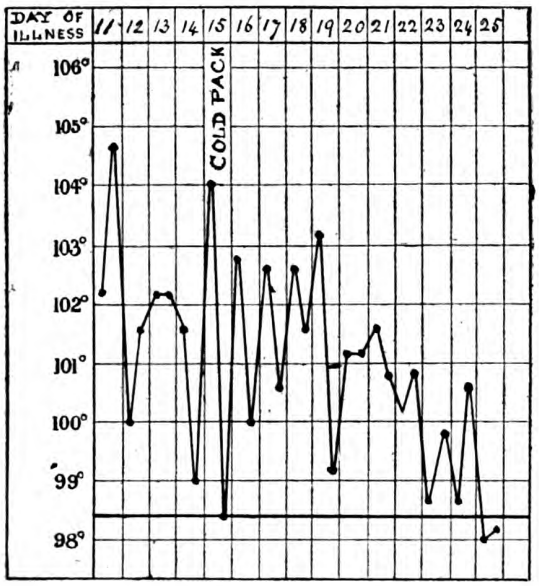


Chart showing the irregular temperature and transition from reversed to normal type.

for several days and all the organs were sound, the suspicion of enteric fever was entertained. On the fourth day it was noticed that the head was retracted and there was slight opisthotonos. The patient was drowsy but answered questions and was irritable when aroused. Both superficial and deep reflexes were abolished except for slight extension of the hallux on plantar stimulation (Babinski's sign). Painful sensation was apparently both diminished and delayed and the *tache méningitique* was easily obtainable. Only slight headache was complained of after the onset and both pulse and respiration were regular. Sitting up was evidently painful owing to spasm of the cervical muscles, when some difficulty in respiration became manifest. The abdomen was not retracted and no enlargement of the spleen could be made out. The bowels were obstinately confined. Strabismus or facial spasm was absent. On the fifth day a well-marked rash, partly erythematous and partly petechial (the former resembling the rose-spots of enteric fever), was noticed on the trunk and extremities and disappeared in the course of a few days. Pain was complained of in one knee and on the dorsum of the foot which was thought to be slightly swollen. On ophthalmoscopic examination the discs were found to be congested, and the pupils reacted slowly to light.

As the case progressed the temperature still remained high—on one occasion reaching 104·6°—and was markedly irregular. During the acute stage the morning reading was considerably higher than that taken in the evening (reversed type), but as the patient began to improve the temperature became lower and showed the normal evening rise. The pulse, regular at first, afterwards became irregular, while the respiration for a short time took on a Cheyne-Stokes type. There were slight ptosis of the left eyelid and photophobia. The reflexes, at first abolished, now became increased, and instead of anæsthesia there was hyperæsthesia. Retraction of the head became more marked, whilst the body was kept in a state of general flexion. There was much irritability, with grinding of the teeth and picking at nose and lips. The child became much emaciated and patches of chloasma appeared on the abdomen and flexor surfaces. The skin over the dorsa and soles of both feet was markedly glossy and shiny owing to the loss of trophic influence (glossy skin of Paget). Occasionally there was vomiting, with a clean tongue, and the urine, which was very dark in colour, was passed unconsciously and smelt very foul.

After about four weeks the patient began to improve, the retraction of the head became less, the pulse and respiration became regular, the hyperæsthesia disappeared, and cutaneous sensibility once again became dulled and the reflexes almost absent. The temperature returned to the ordinary type as convalescence became established and averaged between 99° and 100°. There were still occasional attacks of vomiting apparently brought on by trifling variations in diet or by sudden changes in the weather, especially when accompanied by thunderstorms. The total duration of the illness until the patient was able to leave her bed was three months.

The treatment consisted in the application of an icebag to the nape of the neck and during the severity of the fever another was applied to the vertex. A mixture containing bromide and iodide of potassium was given at first to allay irritability and to promote absorption, but as it sometimes provoked vomiting it was not persevered with. As the collapse became more marked small quantities of brandy were given by the mouth and heat was applied to the extremities, and when vomiting interfered with the retention of food rectal enemata were administered. The bowels were kept open by frequent small doses of calomel.

The origin of the illness was obscure, though it is noteworthy that the only other child in the same house contracted diphtheria three weeks after the onset. The surroundings and sanitation appeared to have been good, except for a tub of pig-wash at the rear of the house which was condemned by the medical officer of health. The diagnosis, which was first suspected to be typhoid fever, was placed beyond a doubt by the well-marked spinal symptoms and the appearance of the purpuric eruption which gives the disease the synonym of "spotted fever." Tuberculous meningitis was negatived by the absence of symptoms pointing to an extensive involvement of the cerebral meninges and of any tuberculous focus elsewhere, nor was any history obtainable of a discharge from the nose or ear as a possible cause of purulent meningitis. The presence of Babinski's sign in this disease has not, I think, been before recorded, and the reversed type of temperature is of interest. Herpes labialis, observed so frequently by Tourdes, von Ziemssen, and others, was absent. No definite arthritis, which is so frequently associated with cerebro-spinal meningitis, could be recognised, though pain was complained of in the knee and over the dorsum of one foot, which was thought to be slightly swollen. Headache was conspicuous by its absence, after the initial onset being only once or twice complained of. It is remarkable that after the dulness of intellect noticed in the early stage the mental faculties were preserved throughout and that the untoward sequelæ recorded by other observers, such as various paralyses and eye and ear changes, did not occur, although the emaciation was profound and only gradually recovered from.

Sale, Manchester.

SOCIETY OF APOTHECARIES OF LONDON.—At the recent examination held by the Society of Apothecaries for assistants, out of 83 candidates only 31 passed. The examination showed very superficial knowledge on the part of those who failed

FOUR CASES IN WHICH PAIN WAS RELIEVED BY SUPRARENAL EXTRACT.

BY E. A. PETERS, M.D., B.C. CANTAB.,
SENIOR CLINICAL ASSISTANT, THROAT HOSPITAL, GOLDEN-SQUARE.

IN spite of the extensive medical literature of the present day it is noticeable that a very small amount of matter dealing with the relief of the pain of cancer exists. The text-books usually instruct that such cases should be treated with rest, nourishment, and antisepsis and remark that morphia locally or hypodermically will be required: and yet few subjects have caused the practitioner of medicine more continued anxiety and trouble. Numerous are the operations which have been devised to eradicate carcinoma, but the requirements of a great many inoperable and re current cases are relief of pain without causing bodily harn . In fact, so great are the sufferings of a patient with a malignant ulcer that it is held to be good treatment, even when radical operations hold out little hope of permanent cure, to suggest surgical treatment with the object of avoiding the otherwise inevitable ulceration. It is agreed that hypodermic injections of morphia are by far the most potent in giving relief to this pain, and though such treatment may be deferred for some time it is eventually used. This use of morphia signalises the last stage, for the effect of morphia on the nutrition of the body is essentially bad. Morphia is destructive (Halliburton); it causes degeneration of the nerve cells and dissipation of Nissl's bodies similar to that brought about by extreme exertion or chloroform narcosis. The nausea, dyspepsia, and lassitude consequent on a dose of morphia are indicative of the same process. Under such circumstances the body has to contend with two poisons, cancer and morphia. Undoubtedly morphia must be used in many cases, but I would urge that local application of suprarenal extract will in many cases postpone the necessity for the narcotic drug.

When liquid suprarenal extract is applied to a part of the respiratory, intestinal, or genito-urinary or other mucous membrane a pallor spreads over the inflamed surface and usually obtains for two hours; even the pain of suppurative ophthalmia is eased somewhat. The pain of subacute inflammations, such as those of cancer and tuberculosis, is quickly and safely eased for two or more hours. Application of the extract once or twice in the 24 hours has reduced the usual pain to a minimum (see Case 1) and apparently the inflammatory condition subsides somewhat (see Cases 1, 2, and 3). The ultimate effect of suprarenal extract on these forms of inflammation cannot be stated; personally I have seen nothing untoward follow its use. Of the various preparations of suprarenal extract which are upon the market the liquid preparations have proved unsatisfactory in my hands. Burroughs and Wellcome have endeavoured to manufacture a reliable "soloid," but except in the case of the earlier specimens these attempts have failed. But an efficient preparation can at any time be prepared from the tabloids of the dried gland produced by that firm. Two tabloids, representing 10 grains of fresh gland, are powdered and placed in a test-tube with 100 minims of boiled water. The test-tube is stood in boiling water for from 10 to 15 minutes. The contents are then filtered; the opalescent filtrate presents a 10 per cent. watery extract, has a specific gravity of 1032, and contains about 2 per cent. of sodium chloride. If required solid cocaine hydrochlorate can be conveniently added to the cooled filtrate. This extract varies widely in keeping properties, and though after the addition of a little camphor it may keep some days it is better to prepare fresh sterile solutions. Some of the 10 per cent. watery extract has been injected subcutaneously into rabbits with no marked ill-effect until a proportion was reached when the 10 per cent. extract of one gramme of suprarenal gland was injected into 1000 grammes of rabbit; at this point a diminution of weight and fall of rectal temperature were noted. When the amount of extract was doubled a great fall of temperature occurred, together with a tendency to sepsis, local gangrene (compare ergot gangrene of our forefathers), and death. If the same proportion holds good in man it would be necessary to inject 22 ounces into a ten-stone man before ill-effects were produced. The fresh glandular extract was not used in any of the above described cases.

The following cases show that the application of a suitable suprarenal extract may be of great benefit in allaying the pain of cancer and other forms of chronic inflammation without any apparent deleterious effect.

CASE 1. *Recurrent scirrhus of mamma.*—The patient, a female, aged 89 years, was seen on July 13th, 1900. The left breast had been removed 12 years ago by Lord Lister. The patient was subject to "eczema." Recurrence commenced four years ago and there was now a red botryoidal mass adherent to a rib with an ulcer on each boss. The ulcers wept slightly. There was some œdema of the surrounding tissues and three dark blue patches. Five shotty and tender glands could be recognised in the axilla. The patient complained of pain around the growth in the axilla and down the back of the forearm to the tip of the middle finger. A weak permanganate lotion and vinolia cream had been used for some time as a local application. Orthoform dusted on relieved the pain, but this treatment was cut short by a severe eczematous dermatitis which spread over the greater part of the body causing some fever. The patient recovered from this in a week's time but complained that the pain due to the growth was becoming worse. On the 21st to ease the pain I prescribed five minims of nepenthe; it had the effect of only partially moderating it. At the end of the week I omitted the nepenthe as the digestion was completely upset. 4 per cent. cocaine was painted on but it did not insure a good night's rest. On Sept. 26th the patient was in fair health, but she complained of being kept awake by the pain around the growth and down the back of the arm and hand. 10 per cent. suprarenal lotion was painted on at 9 P.M. and it gave her freedom from consciousness of the presence of the growth till 6 A.M. She slept well. On Dec. 24th the patient was better. Her tongue was clean and her digestion was active. She went out occasionally for a short walk. The pain was severe at times, but it was decidedly less so than it had been previously to the use of suprarenal extract. The growth was paler and appeared smaller, but it was impossible to say if the growth or the glands were really diminished in size. The suprarenal lotion had been used night and morning for three months and was as effective as ever and a night's rest was secured by the use of the extract.

CASE 2. *Stricture of the œsophagus (? cancer).*—The patient in this case was a woman who came to me on Oct. 7th, 1899, complaining that for three months she had been troubled with mucus which she vomited up with some difficulty before she could effectively swallow food. Solid food always gave trouble and caused pain in the region of the xiphoid process. A No. 20 conical bougie passed, but was grasped near the cardiac orifice. The patient asserted that the bougie on touching the constricted part gave rise to pain such as she had previously experienced. As the patient had not improved after a month of medicinal treatment a No. 21 bougie was employed and it did not enter the stomach. The next note of the patient's case is dated Sept. 5th, 1900. The patient had had iodide of potassium and other drugs which had not prevented the progress of the dysphagia. She could take fluids, and this only after getting rid of the mucus, which collecting induced pain passing from the xiphoid process through the liver to the right side and the axilla. A No. 20 bougie was passed once or twice a month under gas; the mucus ejected was frequently stained with blood. The patient complained that her nights were bad on account of the pain. On Oct. 3rd, 1900, the patient looked ill and she ascribed this to her disturbed sleep. The organs were all apparently healthy. She was directed to sip slowly one teaspoonful of the 10 per cent. suprarenal extract before going to bed. On Dec. 20th the patient was obtaining complete relief by the use of the suprarenal extract and sleeping free from pain till from five to six o'clock in the morning, when she would eject the mucus. She told me that she omitted the suprarenal extract one night and slept well that night. A No. 20 bougie was passed and it induced a return of the old pain, which yielded at once when the suprarenal extract was sipped.

CASE 3. *Tuberculosis of the larynx* (under the care of Dr. Lambert Lack, who has kindly allowed me to publish the notes).—The patient, a man, aged 34 years, was seen on July 17th, 1900. There were œdema and ulceration of the arytenoid projections and the pain was great.

Dr. Lack scraped the affected part and constitutional treatment was instituted. Since then lactic acid paint had been freely used, but the sharp pain passing into the ears was still a source of trouble on breathing, coughing, or swallowing. On Dec. 4th 10 per cent. suprarenal extract was sprayed on at 4 P.M. The patient subsequently reported that the throat was free from soreness for two and a half hours, even on coughing. A dull pain returned, but the sharp pain was absent during the subsequent week. On Dec. 11th the patient described a dull ache in the throat and said that if his appetite would only improve he would get on.

CASE 4. *Periodontitis.*—The patient in this case, when seen on Nov. 10th, 1900, was suffering from periodontitis associated with considerable pain, which came on in paroxysms with shortening intervals. Cocaine, iodine, carbolic acid, and chloroform were all applied locally with little effect. A flat pledget of wool one and a half inches by one inch soaked in 10 per cent. suprarenal extract and kept tucked up between the lip and the gum gave great relief. The pledget had to be renewed every two to six hours. The gum felt dead after the application. A small abscess subsequently formed.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES OF A CASE OF COMPLETE INVERSION OF THE PUERPERAL UTERUS.

BY GEORGE ELDER, M.D. GLASG.,
CONSULTING SURGEON, SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

A PALE, nervous young primipara was delivered by Mr. J. T. Knight of Carlton with forceps in the absence of his partner, Dr. Sutherland. There was but little hæmorrhage; the placenta was easily expressed and the uterus was afterwards felt firmly contracted. The patient's recovery was uneventful until July 31st, so much so that for several days she had been up in her bedroom, on which date Dr. Sutherland had an urgent summons to go and see her as she had been taken suddenly ill. He found her in bed evidently suffering from severe shock, looking more than usually pallid with a very feeble and running pulse. There was also a slight bloody vaginal discharge. After a couple of days' rest she felt so improved that she was anxious to get up, but to this Dr. Sutherland would not consent without previously satisfying himself of her condition by a vaginal examination. This was done on August 3rd and to his surprise he found the uterus completely inverted and lying in the vagina. He thereupon tried to replace it but without effect. On the following day I saw her with him, and as the first attempt to replace the uterus had been so recently made and as urgent symptoms were absent it was thought better to wait a few days before making a second attempt. In the meantime hot antiseptic douches were to be used twice a day and the patient was to lie with her pelvis elevated. On August 11th, there being no amendment in the conditions, the patient was placed under an anæsthetic by Dr. Sutherland, and, with Mr. Knight assisting, the uterus was without much difficulty replaced by manual pressure, and to prevent recurrence the vagina was well packed with iodoform gauze. For the week following she kept her bed, and at the end of this time, her general condition being satisfactory and the uterus being normal in position, she was allowed to get up.

I am indebted to Dr. Sutherland for the above brief record of the case, to which I should like to add a few remarks which suggest themselves. Although this accident occurs, according to authorities, only once in about 144,000 cases of labour, yet, inasmuch as it is a danger to life which may present itself any day in the practice of every practitioner, it seems to me that the recital of every case must of necessity be of value. Given the necessary conditions for it—namely, an increased uterine cavity and general or limited relaxation of its walls—it is found that this accident may occur from several causes, singly or combined: (1) notably and mainly from forcible traction of the cord, although both Tyler Smith and Matthews Duncan held that as a causative factor this was much overrated; (2) from injudicious and violent abdominal pressure; and (3) from irregular muscular action. It is to this last category, which is obviously out of the control of the medical man, that I believe the above-mentioned case to belong; and although the full extent of the mischief did not declare itself until 18 days after labour, it is more than possible that a minor degree of it began then, and this acting as a foreign body in the uterine cavity stimulated the expulsive efforts which in time, assisted by the patient getting up out of bed, completed the process. Another point worthy of note is the small amount of bleeding observed as opposed to many recorded cases where death has been brought about by this cause alone. Manual re-position is generally sufficient for the treatment of recent cases, although one must not lose sight of the fact that the soft uterine tissues are peculiarly liable to bruising, with sepsis as a possible sequel, and to perforation and rupture.

Nottingham.

NOTE ON AN ANOMALOUS FORM OF QUININE ERUPTION.

BY G. NORMAN MEACHEN, M.B., B.S., L.R.C.P. LOND., M.R.C.S. ENG.,
SENIOR RESIDENT MEDICAL OFFICER, TOTTENHAM HOSPITAL, N.

A MARRIED woman, aged 23 years, was admitted into the Tottenham Hospital on Jan. 3rd, 1901, for pain and swelling of the left leg due to a chronic periostitis of the tibia. As she was pale and had had some fever, one grain of the sulphate of quinine was given with half a grain of the sulphate of iron in a mixture every four hours. Five days later numerous scattered reddish papules appeared on the face, shoulders, and extensor surface of the left leg. In the latter situation the papules, which were elevated above the surface, soon became vesiculo-pustular and showed some tendency to a circinate grouping. Itching was not a prominent feature and the pustules dried up and became absorbed without breaking, leaving a brownish discoloration. There was no faucial angina and the only other symptom of cinchonism present was headache.

The above case is instructive as showing that the quinine exanthem may, though rarely, exhibit itself in a pustular form. Morrow[1] states that although the prevailing type of the quinine eruption is erythematous, yet exceptionally it may be eczematous or purpuric. In two out of his 60 cases it was "vesicular." Moreover, the toxic effects of quinine as manifested in the skin are more commonly generalised, yet Elliott[2] of New York relates a case in which a bullous eruption due to quinine appeared on the feet. In this case it was on the leg that the rash was first noticed. I am indebted to Dr. Hooper May for kind permission to publish these notes.

Tottenham, N.

NOTE ON THE ADMINISTRATION OF AN ANÆSTHETIC TO A PATIENT WITH DOUBLE ABDUCTOR PARALYSIS.

BY OTTO F. F. GRÜNBAUM, B.C. CANTAB.

A RATHER thin, pale man, aged 24 years, was admitted to the West London Hospital for hæmatocele on Dec. 10th, 1900, under the care of Mr. Keetley, when an operation was deemed advisable. Upon the operation table the patient volunteered the information that he thought that his heart was weak, because he became breathless on running. (Many patients make these remarks under similar circumstances.) He was assured that his heart had been examined and showed no signs of disease and the administration of the anæsthetic was begun. The patient took gas well; he passed under the influence of ether and had nearly lost the cyanosis due to gas when he ceased breathing. A gag was inserted and his tongue was drawn well forwards, but,

[1] Drug Exanthemata, New York Medical Journal, 1880.
[2] Journal of Cutaneous and Genito-Urinary Diseases, New York, 1888.

no signs of voluntary respiration occurring, artificial respiration was resorted to without delay. Since the pupils continued to dilate while the passage of air into the lungs was accompanied by considerable noise, tracheotomy was suggested but not performed because the nature of the puff of air pressed out of the thorax during artificial respiration proved that there was a satisfactory air entry. Five minims of liquor strychninæ were injected. Two minutes later the pupils began to contract and after six minutes voluntary respiration with loud stridor began. Shortly afterwards the patient regained consciousness and recovered sufficiently to sit in a chair before the fire. He continued to gasp for breath, but showed that he had returned to sense and sensibility by a refusal to inhale any medication. The stridor gradually decreased and 40 minutes later it had disappeared. The following day the patient was feeling quite well. The character of the dyspnœa which occurred under anæsthesia suggested some laryngeal stenosis. On questioning the patient further about his breathlessness on exertion it was elicited that any exertion produced noisy stridulous breathing and, further, that this difficulty had existed as long as he could remember. On the 14th Dr. J. B. Ball was asked to examine the patient. He reported that both vocal cords lay near the middle line and on deep inspiration approached each other slightly, still further narrowing the glottic aperture. The condition appeared to be that of complete bilateral abductor paralysis. The appearance was not exactly typical as there was a slight obliquity in the line of the glottic aperture.

The object of recording the case is to add to the list of pathological conditions which may lead to death during the administration of an anæsthetic, but which (without exceptional examination), may not give any evidence of their existence during life or on the post-mortem table, however minute an investigation be made.

SAMARITAN FREE HOSPITAL.

A CASE OF HYSTERECTOMY FOR UTERINE FIBROID IN THE FIFTH MONTH OF PREGNANCY; RECOVERY.

(Under the care of Mr. ALBAN DORAN.)

A WOMAN, aged 40 years, a patient of Dr. J. Reid of Hammersmith, was admitted into the Samaritan Free Hospital on Sept. 24th, 1900, under the care of Mr. Alban Doran, on account of an abdominal tumour. She had been married for two years and had never been pregnant, but no period had been seen since May 25th, 1900, though she was quite regular up to that date. In April she strained herself when lifting a weight, and then for the first time she noticed a tumour. On Sept. 24th Mr. Doran examined her and discovered a firm, irregular mass at the level of the umbilicus and to the left, another hard mass in Douglas's pouch, and a softer tumour in the lower part of the abdomen, covered by intestine. All three were continuous, moving together. The cervix was high up under the pubes. The patient was sent home, it being intended to determine how far the growth would interfere with the advance of the pregnancy. On Oct. 9th the tumour was much larger, the souffle being heard plainly; the upper mass had shifted from the left at the umbilical level to the right, some way above the umbilicus. The cervix had risen still higher above the pubic arch, whilst the mass in the pelvis was not only larger but was now fixed. The breasts were getting full and an areola had developed around each nipple. Thus the fibroid was interfering seriously with the pregnancy.

The patient was readmitted into the hospital on Oct. 28th, when the pelvic mass was still more fixed. To attempt reduction would be dangerous, as the soft uterus lay between the hard pelvic mass below and the equally resistant mass above and might thus have been ruptured. Dr. Hubert Roberts examined the patient and was of opinion that hysterectomy would be advisable at once. Removal of the fœtus through the vagina would, considering the relations of the parts concerned, involve the danger of rupturing the uterus or setting up inflammation of the tumour. As for allowing the pregnancy to go on till term Cæsarean section would then be necessary, but the pelvic mass would by that time be very harmful to structures around it and pressure symptoms were already beginning. Delivery through the vagina at term would be impossible. The case was explained to the patient and she preferred immediate operation.

Mr. Doran operated on Nov. 1st, Mr. Butler-Smythe assisting and Dr. G. B. Flux administering chloroform. On opening the abdomen the pregnant uterus came in view. The upper mass was larger than it appeared on palpation; it reached upwards and backwards behind intestine, almost touching the liver. The uterus was raised and then the pelvic mass came into view; it sprang from the back of the uterus just above the cervix. With a little manipulation Mr. Doran succeeded in getting the pelvic mass up; it was firmly fitted into the pelvic cavity. The cervix was narrow. The ovarian and round ligament and uterine arteries on both sides were secured and the uterus was amputated. The patient's pelvis was then elevated, so that the stump could be easily kept in view whilst the flaps were united by suture. Lastly, the abdominal wound was closed.

Recovery was uninterrupted and the patient was discharged on Nov. 29th. On Feb. 1st, 1901, she was in excellent health and free from any discomfort. The uterus, with membranes intact, was sent to the Museum of St. Bartholomew's Hospital and has been mounted so as to show the fœtus and the relative position of the two myomatous growths.

Remarks by Mr. ALBAN DORAN.—Pregnancy in a uterus affected with myoma is specially serious when the new growth is situated in the posterior part of the lower segment or in the cervix for during pregnancy a fibroid tends to grow rapidly. Over 12 years ago I demonstrated the marked hyperplasia which occurs in the muscle-cells of a myoma in a monograph published in the Transactions of the Obstetrical Society of London.[1] When the growth springs from the fundus pregnancy may continue to term and labour may end spontaneously, whilst during the puerperium the tumour, homologous histologically with the uterus, will share more or less in the process of involution; but when the tumour springs from the back of the lower segment of the uterus pregnancy cannot proceed normally, pressure symptoms set in early, and operative interference becomes necessary. These are the cases where the presence of a fibroid is often unknown until revealed by the complications which arise during gestation. I have recently operated upon the above case, where I had he great advantage of being able to watch the pregnancy until it became evident that a tumour lay below and behind the uterine cavity and could not be pushed up out of the pelvis which it blocked.

Several somewhat similar cases have been recorded. McMurtry[2] operated on a woman, aged 34 years, in the fifth month of pregnancy. The only abnormal symptom observed by the patient before this pregnancy was menorrhagia, which had existed for two years. The pelvis was blocked by a fibroid in the posterior wall of the uterus, pressing on the rectum and bladder; the cervix was out of reach, high up under the pubes. Retro-peritoneal hysterectomy was performed with success. Cripps's[3] patient was 44 years of age, the menstrual history was irregular, but the pregnancy had lasted over two months, the pelvis was blocked, and the cervix was high up anteriorly. In amputating the uterus, though the membranes were not ruptured, much dark, old clot escaped from the uterine cavity. The operator therefore flushed out the peritoneum and then for a reason not explained in the report passed a Keith's drainage-tube into Douglas's pouch. The operation was a retro-peritoneal hysterectomy and the specimen, like my own, is preserved in the museum of St. Bartholomew's Hospital. Tauffer's case[4] was somewhat similar. The patient was a nullipara, aged 27 years; several fibroids

[4] Monatsschrift für Geburtshülfe und Gynäkologie, November, 1900, p. 658.

occupied the uterine walls, one blocking the pelvis. Retro-peritoneal hysterectomy was successfully performed in the middle of the fourth month. Horrocks[5] removed by retro-peritoneal hysterectomy a uterus in the fifth month of pregnancy where the fibroid, which caused pressure symptoms, lay chiefly to the left of the uterine cavity. Before operation he diagnosed this condition by distinguishing on palpation a bilobed tumour, the right lobe being the softer and bearing a ridge formed by the round ligament, Fallopian tube, and ligament of the ovary. As will be explained, the tumour was not of the same type as those in the four cases already noted.

The case of Gemmell,[6] of Liverpool, was different surgically from any of the above. The patient was a nullipara, aged 30 years; retention of urine and abdominal pain came on suddenly at the third month of pregnancy. The pelvis was blocked by the tumour and the cervix lay high up in the pelvis and to the left. The abdominal cavity was opened and the pelvic tumour was drawn up to the incision, thus rotating the pregnant uterus to the left. The tumour was situated on the posterior wall of the uterus above the level of the internal os and was of the size of a large orange; it was enucleated easily. The bleeding was free but was controlled for a time by sutures; free oozing set in, however, so that the abdominal wound had to be enlarged; then the uterus was brought out and all bleeding points were controlled. The pelvis was flushed and very rightly no drainage was employed, the wound being closed. The pregnancy went on till term; the forceps was found necessary to deliver the child. The mother did well. This case may be instructively compared with that of Horrocks, already noted above, where the operator found that the attachment of the tumour to the uterus was more by vessels and loose connective tissue than by perfect continuity so usual in fibroid disease. After removal it was enucleated from the left broad ligament with the greatest ease. Horrocks, therefore, states that in future he will begin on the tumour side so as to make sure whether it could be removed alone or not, so that the gravid uterus might be saved. Gemmell's enucleation seems to have answered well, but such a procedure is not always feasible and when so the presence of large veins renders it dangerous in a pregnant subject even when the most approved precautions are taken. Horrocks's tumour, on the other hand, was in the broad ligament, really separate from the uterus; still, a conservative operation like enucleation may be more dangerous than hysterectomy when pregnancy has advanced beyond the second or third month.

Two cases where the conditions differed in other respects from what existed in my own case are worth recording. Keiffer[7] operated on a case where a fibroid mass reached to the epigastrium and blocked the pelvis, flattening the cervix against the pubes. Pregnancy had advanced to the fifth month. Retro-peritoneal hysterectomy was performed. The pregnancy had developed in a retroflexed uterus, the fundus being occupied by the mass which filled the pelvis. The antero-superior part of the uterine wall formed the uppermost part of the tumour, whilst only a small part of the inferior segment had been able to dilate so as to hold the ovum. This case is instructive in relation to hysterectomy for fibroid disease in pregnancy; it shows that the possibility of retro-displacement—perhaps with no new growth at all—must be taken into account in diagnosis. As there was some shock after the operation Keiffer gave the patient sparteine, a compound which I have recently found very beneficial after severe abdominal operation.

I may note William Duncan's case[8] where the fibroid occupied the cervix. The patient was a multipara, aged 38 years; the tumour had been noticed for two years and irregular hæmorrhages followed an abortion 18 months before operation. The pregnancy had reached the fifth month. Duncan prefers retro-peritoneal hysterectomy to pan-hysterectomy, but in this case there was no alternative but to remove the entire uterus.

Thorn of Magdeburg[9] recently operated on a woman, aged 41 years, who had been married seven months previously. The periods had ceased for three months and acute symptoms, such as are seen in twisting of the ovarian pedicle, set in. At the operation the uterus was found to be twisted 180 degrees on the cervix, through a heavy myoma in its anterior wall. The tumour and a smaller myoma in the fundus were enucleated, and pregnancy went on undisturbed, but no mention is made of the labour.

The operative treatment of uterine fibroid late in pregnancy lies beyond the subject of these remarks. Dr. Amand Routh's recent report of a case of retro-peritoneal hysterectomy at the thirty-fourth week[10] is of high interest; the mother and child were saved. The discussion which followed the reading of this paper deserves perusal. The whole question of pregnancy and labour complicated by fibroid disease is ably discussed in a recent treatise by Dr. John Phillips.[11] He shows under what conditions a fibro-myoma may have no prejudicial effect on gestation and parturition and concludes by laying stress on the point to which I drew attention at the beginning of my remarks—namely, that whilst fibroids of the anterior wall are of little import those on the posterior are serious. The anterior segment is shorter and ascends during labour; the posterior is longer and descends. When, as in my case, there is a myoma in the lower part of the posterior segment not only is dystocia certain but troubles begin long before term.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Intestinal Sand.—The Limitations of Enterectomy.

A MEETING of this society was held on Feb. 26th, Dr. F. W. PAVY, the President, being in the chair.

Sir DYCE DUCKWORTH and Dr. ARCHIBALD GARROD related a case in which Intestinal Sand was present and was accompanied by diarrhœa. Having commented on the infrequency with which such cases had been reported in England as compared with continental records Sir Dyce Duckworth and Dr. Garrod sketched the course of the illness of their patient, a married woman, aged 33 years, living in healthy surroundings save for the supply of water, which was hard, and contained organic impurities. The family history showed that the patient came of a gouty stock and the patient had, after her last confinement, suffered from peri-anal eczema accompanied by looseness of the bowel. The present ailment began in January, 1900, with a very intractable diarrhœa accompanied with internal rumbling and purring noises, there being six or eight loose motions in each 24 hours. In the middle of February the patient took to her bed and was ordered an exclusively milk diet with lime-water. This treatment lessened the diarrhœa to three or four motions each day, sometimes attended with the passage of mucus. On March 18th sand was discovered in the motions, and it was found subsequently in all in which it was looked for. Early in May Sir Dyce Duckworth saw the patient with Dr. Garrod. She was pallid and sparely nourished. The thoracic organs were healthy. On examining the abdomen it was found that the colon and its sigmoid flexure were, though empty, too readily palpable and apparently thickened in their walls. The right kidney was moveable. There was a slight degree of pyrexia at this period, the temperature rising occasionally to 100° F. or a little above this. Specimens of the sand were obtained and submitted to examination. It sufficed to say that it much resembled at first sight a deposit of uric acid, being of reddish-brown colour and finely gritty. It was insoluble in cold and boiling liquor potassæ and readily soluble in boiling nitric acid. Under a low power of the microscope particles of various shapes and sizes were seen, of a brilliant

reddish-brown hue, and translucent. The patient was confined to bed and kept on milk diet. For medicine salicylate of bismuth and bicarbonate of sodium were given in mixture. Under this treatment the diarrhœa was somewhat checked and the general health improved. In July the patient was advised to go to Plombières. There she took baths and had rectal douches and drank the water in small quantities. All vegetable food was withheld and digestion was found to be much more comfortable without it, as it caused immediate distension. She lost 10 pounds in weight while at Plombières. The next month was spent in Folkestone with some benefit and some weight was regained. In November she was rather pallid and languid, was easily tired on exertion, but had regained her usual weight (9 st. 2 lb.). The large bowel no longer appeared thickened, as it did six months previously, but there was tenderness on pressure about the splenic flexure of it. There was still a looseness of the bowel, from two to four actions occurring daily, but no sand was passed. Her diet was altogether of animal food, and a little whisky was taken with one meal. The urine was turbid with lithates and deposited uric acid. The tongue was large, flabby, and thinly grooved. A mixture with liquid extracts of cinchona and bael and tincture of cinnamon was ordered, and milk with natural seltzer water was added to her diet. The catamenia were regular. She returned home about the middle of the month. This case presented most of the characters that had been described in the few instances of the disorder that were already on record. It was, however, remarkable for the little pain which was experienced. In most examples of enteric lithiasis this appeared to be a marked feature, occurring in paroxysms, lasting several hours, somewhat akin to those associated with biliary and renal colic, and attended with much flatulent distension and vomiting. When washed and dried in the air the gritty material passed with the motions had the appearance of a fine sand. Its ground colour was a deep brown, with an admixture of pale or almost colourless particles. Under a low power of the microscope the individual granules were seen to have a great variety of shapes: some were roughly oval, some were oblong or even rod-like, and others, again, were of very irregular outline. Their colour varied from yellow to a warm brown. Some were translucent and others were opaque with the exception of their edges. Some had a finely granular appearance, but none of them showed any indication of crystalline structure. The air-dried sand lost considerably in weight at 100° C., owing to the expulsion of water from the organic basis, and the percentages of water and of organic and inorganic materials contained in it were found to be as follows: water, 12·40; organic material, 26·29; and inorganic material, 61·31. The inorganic residue left after combustion over a Bunsen's burner had a bluish-white tint and contained only a few dark particles. With the exception of such particles it was completely soluble in hydrochloric acid. This residue was submitted to analysis and was found to have the following composition: calcium oxide (CaO), 54·98; phosphorus pentoxide (P_2O_5), 42·55; carbon dioxide (CO_2), 2·20; and residue, containing traces of magnesium and iron, 0·47. The presence of magnesium was beyond doubt, but the quantity was extremely small. Calcium phosphate was clearly the chief mineral constituent.—Dr. A. CROMBIE thought that the affection must be more common in India than in this country. In the course of 10 years he had met with three cases in a hospital of 150 beds. The chief symptom was colic, which was sometimes intense and severe. The severity of the symptoms varied directly with the amount of sand present in the stools. In two cases immature acari were found present in the stools. He had once found sand in the stools of a pig.—Dr. T. J. BOKENHAM had met with intestinal sand in the stools of a young woman of neurotic temperament. Its presence was accompanied by colic and diarrhœa. The sand presented slight differences as compared with that in the case related by Sir Dyce Duckworth and Dr. Garrod.

Mr. ARTHUR E. BARKER reported two cases of Enterectomy bearing on the Limitations of the Operation. In the first case glycosuria was present and in the second five and a half feet of small intestine were removed for gangrene from a woman, aged 76 years. The first patient, a married woman, aged 58 years, was admitted into University College Hospital on Oct. 3rd, 1900, under the care of Dr. G. V. Poore. She complained at this time of great pain above the umbilicus and obstinate constipation. She was known to suffer from diabetes and later was found to have 6·6 per cent. of sugar in the urine. The pain had begun eight months previously and she was obliged to remain in bed from the middle of May to the end of June, 1900. The abdomen, on inspection, looked like that of a healthy woman who had borne many children (10). There was tenderness above and to the left of the umbilicus, and here an oblong tumour could be felt. It was decided to distend the stomach with air and then after evacuating it to inflate the colon. When the stomach was distended the tumour was a little less evident but was otherwise unaltered. On distending the colon, however, the tumour was pushed to the right iliac fossa and reduced in size. From this we argued that it was probably seated in the transverse colon and was associated with more or less intussusception of a ring-like growth of carcinoma into the distal portion of the bowel. The patient being in fair condition except for the glycosuria it was determined to attempt removal of the growth. Enterectomy was performed on Oct. 25th, 1900, four and a half inches of bowel being removed. The patient bore the operation well. The temperature remained below 100° F. for the first nine days, during which she steadily improved. There was no vomiting except a mouthful soon after the operation. Feeding by the rectum was kept up for four days and small quantities of fluid were given by the mouth from the second day onwards. Morphia was given, at first two or three times daily, but on the third day Mr. Barker began to administer codeine phosphate in one-grain doses hypodermically three times daily on account of the sugar in the urine, which was shown on the fourth day to amount to 6·6 per cent. From this day it steadily declined in amount until on the ninth day it was only 2 per cent. It diminished now still more rapidly when the codeine in the same amount was given by the mouth until the thirteenth day, when it disappeared altogether, only to reappear once to the amount of 2·8 per cent. on the seventeenth day, when it was found that the patient had surreptitiously eaten some sugar and also grapes. After this sugar was either totally absent or only found in a mere trace until the end of convalescence. Complete recovery ensued, only delayed by some local sloughing of omentum and mesentery. Thus in a condition of marked glycosuria repair of the intestine was shown to be possible. The second case was that of a feeble old woman, aged 76 years, who was admitted into University College Hospital on Jan. 10th, 1901. She had always enjoyed good health, but in 1870 had undergone ovariotomy. She had had no children. For two years she had had a large ventral hernia in the ovariotomy scar. On Jan. 8th and 9th she had not felt well and had complained of some pain in the abdomen but was not sick. At 10 A.M. on Jan. 10th the patient was seized with severe pain in the abdomen and vomited the contents of the stomach slightly bile-stained. The hernial tumour was tender and more swollen than usual. There was no more sickness and no motion or flatus was passed. Mr. Barker immediately opened the abdomen through the old scar and about a pint of dirty blood-stained fluid with a fishy odour gushed out. A loop of blackened small intestine was now seen of about three feet in length strangulated through the omentum. The gut had not entirely lost its lustre, but was very foul and distended tightly with dark blood-stained fluid. The peritoneum was not cracked, but hæmorrhages existed beneath it in several places, and a few of the subperitoneal venules were thrombosed. The extremely foul and fishy odour of the gut and fluid around it determined Mr. Barker to remove it as its recovery seemed hopeless. He therefore cut away five and a half feet of the bowel and anastomosed end to end as rapidly as possible. The time taken for this part of the operation was 44 minutes, the whole operation to the last stitch requiring 63 minutes. During the operation, which was well borne, 12 ounces of normal saline solution were slowly injected subcutaneously. The whole of the lower part of the abdomen was filled up with very hard fibroids of the uterus which reduced the amount of space for working very much. Recovery was uninterrupted. Commenting on these cases Mr. Barker observed that the first recalled what had been brought before the society concerning diabetic gangrene, in which condition, in spite of extensive arterial thickening, good results had been obtained. With regard to extensive excision of the bowel it seemed probable, from experiment and observation, that in younger patients who survived the operation a compensatory

hypertrophy might take place in the small bowel left behind which might make up for the loss. It seemed also to be suggested that the resection was better tolerated the lower down the intestinal tract it was done.—The PRESIDENT observed that it was important to distinguish between the alimentary and the composite forms of glycosuria. In the former the condition could be removed by diet; in the latter dangerous bodies, such as acetone, diacetic and oxybutyric acids, were present in the blood besides sugar. The surgeon could be helped greatly by the physician in these cases, and the latter form was to be taken as contra-indicating all but imperative operations.—Sir THOMAS SMITH recorded a case in which a man not previously known to be diabetic accidentally scratched his finger and within a week succumbed to septicæmia with gangrene of all four extremities.—Sir DYCE DUCKWORTH observed that in spite of the immense advantage of antiseptics surgeons would still need to be judicious in operating on diabetic subjects.—Mr. BARKER, in reply, said that in his first case he thought that the continuance of marked glycosuria during the first 10 days—the most important period of repair—was of interest.

MEDICAL SOCIETY OF LONDON.

Painless Pyonephrosis without Fever.—Fibroids of the Cervix Uteri.

A MEETING of this society was held on Feb. 25th, Mr. J. H. MORGAN, the President, being in the chair.

The PRESIDENT read a communication from the Home Secretary acknowledging the recent loyal address from the society to King Edward VII. and conveying His Majesty's thanks for the same.

Mr. ALBAN DORAN read a paper on Painless Pyonephrosis without Fever; nephrectomy; recovery. He brought forward this case because he had found that though painless calculous pyonephrosis was by no means unknown surgeons were too often induced when making a diagnosis in a case of painless enlarged kidney to exclude calculous pyonephrosis on the ground that that disease must always be more or less painful. The patient was a woman, 38 years of age, who had borne eight children, the youngest of whom was five and a half years old. Her husband had been subject to stricture and cystitis. For a few months she herself had suffered from purulent vaginal discharge. For a year she had noticed a swelling in the right side; it ached when she put on her stays, but when undressed she was always comfortable. There was no history of rigors, fever, hæmaturia, or renal colic. A large moveable kidney lay in the right flank; it was not tender. The urine occasionally contained albumin. Mr. Doran exposed the kidney by a Langenbeck's incision; it was extracted with the greatest ease; the circumrenal fat was quite healthy. The ureter was reduced to a thin cord. The left kidney felt slightly enlarged but of normal consistence. The patient was in good health three months after the operation. The right kidney had become a cyst containing about a pint of what Mr. Shattock reported as pure *pus laudabile* without a trace of tubercle. The upper part was dilated into an almost unilocular cyst through complete stricture of the ureter at its origin from the pelvis. The lowest calices were blocked by a small rough calculus in the infundibulum; they formed a bilocular cyst. In one dilated calyx a piece of mulberry calculus lay loose. In this case the infection was probably gonococcal and therefore ascending. A calculus blocked the lower calices but the cause of the blockage of the ureter was not so evident. It seemed that a calculus had caused it and then come loose. Similar cases were quoted. Mr. Doran observed that it was fortunate that the operation was not delayed till adjoining structures had been involved. He was of opinion, like Noble of Philadelphia, that the removal of a suppurating kidney allowed its fellow to do its work better. He considered that abdominal nephrectomy was preferable in such a case to the lumbar method. The absence of pain recalled the pathological researches of Mr. Bruce Clarke and certain clinical experiences of Mr. Henry Morris and Mr. Murray of Cape Town. The absence of fever was remarkable; the patient went about with one kidney converted into a bag of pus and yet appeared to be in excellent health and was able to attend to heavy domestic duties.—The PRESIDENT remarked that the case was almost unique; the absence of pain and fever with such a kidney was quite exceptional. He asked what had been Mr. Doran's experience of the internal administration of boric acid in conditions of urinary sepsis.—Mr. BUTLER-SMYTHE observed that the degree of pain was to some extent dependent on the patient's mental constitution. He asked why the ureter had not been dropped back into the peritoneal cavity after dis infection of its divided end; he had done this in two cases without any ill effect.—Mr. DORAN, in reply, said that following Mr. Knowsley Thornton's lead he preferred in suppurative conditions to treat the ureter as he had done, bringing it out of the lower end of the wound. He had known a lumbar abscess to follow when the ureter had been dropped back. In non-suppurative conditions the circumstances were different. He had found that the administration of 10 grains of boric acid three times daily had been followed in several cases by an improvement in the urine. Whether this was *post* or *propter* he could not say. The absence of fever might be due to the gonococci, which he thought were the cause of suppuration in this case, having perished.

Dr. A. H. N. LEWERS read a paper on Fibroids of the Cervix Uteri. He said that fibroid tumours arising in the cervix were much less common than those met with in the body of the uterus. The ordinary classification of the latter into interstitial, subperitoneal, submucous tumours, and fibroid polypi served equally well in considering fibroid tumours of the cervix. The present paper dealt only with interstitial and subperitoneal fibroids of the cervix. When these tumours originated in the cervix and reached the size of a cocoanut and upwards they became fixed, with fixation of the rest of the uterus as a consequence, and they also exercised pressure on the neighbouring parts, especially on the bladder and ureters. As a matter of fact, troubles connected with micturition figured prominently in the history of such cases. These tumours were generally solitary, whereas fibroids of the uterine body were most frequently multiple. The effect on menstruation varied; sometimes there was profuse menorrhagia; sometimes, however, menstruation was scanty or absent for many months at a time. When the tumour was interstitial and solitary the body of the uterus, practically unaltered, could be felt perched on the top of the tumour in the neighbourhood of the umbilicus. Four specimens from the cases fully recorded in his paper were shown at the meeting. In Case 1 there was a large solitary interstitial fibroid of the anterior cervical wall. In this case the patient had been rendered profoundly anæmic by menorrhagia. In Case 2 there was a large solitary interstitial fibroid of the posterior cervical wall. Difficulty in passing urine and at times inability to hold it, with pain about the lower abdomen and back, were the chief symptoms. Menstruation was scanty and only occurred three times in the two years before the patient came under observation. In both cases intra-peritoneal abdominal hysterectomy with formation of a cervical stump was performed and both cases did well. In Case 3 the tumour was a large subperitoneal fibroid weighing 9½ lb., springing from the back of the cervix and raising the peritoneum from Douglas's pouch, the whole of the left side of the pelvis and the left iliac fossa. At the operation there was no peritoneal cavity to the left of the incision below the umbilicus. The sigmoid flexure was seen above and to the right of the umbilicus. Abdominal hysterectomy, intra-peritoneal, was performed, there being enough cervix below the origin of the tumour to form a stump. This case also did well. In Case 4 there was a fibroid of the left side of the cervix, partly interstitial and partly subperitoneal. There were in this case also several fibroids in the body of the uterus and a small ovarian cyst on the left side. This case was treated by abdominal pan-hysterectomy and did well. As regards diagnosis, it was to be remembered that in all cases of large interstitial fibroid of the cervix the os uteri became dilated sufficiently to admit the finger, which then came on a part of the fibroid. It was important not to mistake the condition for that found in cases of submucous fibroid of the cervix or body of the uterus. The latter kind of fibroid could be safely treated from below, whereas in cases of large interstitial fibroid of the cervix an attempt to remove the tumour from below by *morcellement* would most probably either fail altogether or prove disastrous.—Mr. DORAN said that he approved of the operative measures that Dr. Lewers had adopted in his cases. The operation of pan-hysterectomy was dangerous when the cervix was dilated owing to the nearness of the ureters. As

a rule, when a fibroid was as large as a cocoanut it called for removal.—Dr. W. GOW thought Dr. Lewers's experience of cervical fibroids exceptional; they were usually set down as constituting about 3 per cent. of all diagnosable cases of fibroids. The physical signs were sometimes misleading, as one or other lip of the os uteri being stretched over the growth might simulate a polypi and tempt the surgeon to operate from the vagina, though he (Dr. Gow) agreed with Dr. Lewers that they should be operated on from above. He thought that the plan of leaving ligatures long and bringing them down into the vagina might lead to suppuration.—Dr. AMAND ROUTH said that it was important to know that cervical differed from corporeal fibroids in being almost always single. He had found help in diagnosis by passing the sound and locating its end through the abdominal wall. In one case he had tied one of the uterine arteries per vaginam. This had been followed by shrinking of the growth.—Dr. J. D. MALCOLM thought that in some cases the tumour could be removed per vaginam. He had so removed one cervical fibroid. He tied a few arteries and packed the cavity with gauze. The patient made a good recovery and had the advantage of retaining the uterus intact.—Mr. BUTLER-SMYTHE felt that such cases as Dr. Lewers had operated on would have fared badly in the hands of a beginner or with the older methods of operating.—Dr. LEWERS, in reply, said that he adapted the operation to each case. He had no objection to pan-hysterectomy in itself, but he agreed with Mr. Doran that it was dangerous when the cervix was dilated. He thought the plan of tying the uterine arteries exposed the patient to the risk of sloughing of the tumour. He thought that only the smaller cervical fibroids could be safely enucleated from below.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 22nd, Sir R. DOUGLAS POWELL, the President, being in the chair.

Dr. STCLAIR THOMSON showed a woman, aged 29 years, with a large irregular, soft Swelling in the Region of the Upper Half of the Right Sterno-mastoid. It was elastic and fluctuating and was neither adherent nor inflamed. She was positive that the swelling commenced just before her marriage (at the age of 27 years) as a small lump on the right side of the neck. This increased during pregnancy and became larger after her first child was born in September, 1900. Mr. Bland-Sutton had stated that congenital serous cysts of the neck were "always noticed at or immediately after birth." Possibly, as they originated below the deep cervical fascia, the one in this case escaped notice until it had made its way through this membrane and had become superficial.—In reply to Dr. A. E. T. LONGHURST Dr. THOMSON said that owing to the deep extensions of the growth he thought it better not to operate upon it.

Dr. J. S. RICHARDS showed a child, aged six years, whose Knee was Excised some time anterior to 1897. A flail-joint resulted and amputation was performed through excision of the scar (1898). The outer portion of the lower end of the femur continued to grow, while there was arrest of growth of the inner portion with resultant hook-like curve.

Dr. H. D. ROLLESTON (for Dr. F. W. BURTON-FANNING) showed a case of Progressive Myositis Ossificans. The patient was a male, aged 33 years. The disease began at the age of eight years. The patient's father had suffered from the same disease. The patient was married and had a daughter, aged seven years, who had not shown any sign of the disease. All four limbs were almost fixed, thus resembling Marie's rhizomelic spondylosis; the spine, except in the cervical region, was rigid from ossification of the muscles. Respiration was diaphragmatic and the patient could not sit down; he could just walk. Movement of the temporo-maxillary joint was greatly limited. The thumbs were natural but the great toes were markedly dwarfed (microdactyly). There was ankylosis of the terminal phalanges on the great toes and on the fourth toe on the right foot. There were exostoses around the knee-joints and one of the size of a marble on the left side of the chest. The ossification of the muscles was very widely spread.—In reply to the PRESIDENT'S question as to what treatment had been adopted Dr. ROLLESTON said that he had given thyroid without any good effect and that he was now trying salicylate of soda, but as yet he could not say that the patient had benefited from it.

Dr. HUGH THURSFIELD (for Dr. A. E. GARROD) showed a boy, aged 10 years, who came to the hospital for Enlargement of the Right Elbow and Left Knee which had been present for four years. He had had occasional attacks of abdominal pain, which passed off quickly, and returned only at long intervals. The swellings of the joints began four years ago and had steadily progressed. The boy had congenital ptosis and enlargement of joint, but was otherwise healthy and intelligent, though rather dull mentally.—Dr. ROLLESTON referred to a case that had been under his care where bursal swellings about the joints had been present from early life, and the patient had a cretin-like aspect, similar to that of the patient now under consideration. He thought that part of the abnormality might be caused by tuberculous infection.—Dr. WILLIAM EWART said that the patient appeared to be suffering from nasal obstruction.—Mr. JACKSON CLARKE thought that this case belonged to a class examples of which had been shown before the society as differing both from cretinism and achondroplasia.—Mr. T. H. KELLOCK asked whether the patient's heat-sense and reflexes had been tested. The ptosis and weakness of the limbs were such as were observed in chronic hydrocephalus.—Dr. THURSFIELD, in reply, said that tuberculosis had been suspected at first, but the general opinion of those who had seen the patient was that the condition was allied to cretinism though not identical with it.—The PRESIDENT proposed that it would be useful to submit the case to a committee.—This was carried.

Mr. BETHAM ROBINSON showed a case of Enlargement of the Right Foot. The patient was a male, aged 38 years, who 19 months ago had a definite injury to his great toe, followed by swelling, and the foot was said to have turned black. A few days afterwards lumps were noticed on the right shoulder, on the outer side of the right wrist, and over the right knee. These went away by themselves at the expiration of a few days. This was succeeded by great loss of flesh, for which he was dieted, but he did not know if his urine was abnormal at the time. There was some suppuration about the toe-nail, which had continued slightly up to the present date. He had now gigantism of the right foot, especially of the great and fifth toes and over the tarsus. There was thickening of the phalanges and metatarsal bone of the great toe, with some looseness and crepitus in the joints, also thickening of the fifth metatarsal. An x-ray photograph showed bony thickening about the phalanges and metatarsal bones of the first toe and over the same bones of the fifth toe. He had neuralgic pains about the leg and on both sides his patellar reflexes were feeble. There was no difference in the size of the legs or arms, but there was some neuralgic pain down the left arm. The crests of the ilia seemed a little thickened. There was a very marked bend in the lower cervical and upper dorsal region of the spine. The bones of the head and face were normal. The pupils responded actively to light.

Mr. RAYMOND JOHNSON showed a case of Actinomycosis of the Skin in the Parotid Region. The patient, a Russian, aged 31 years, went to University College Hospital on Feb. 2nd on account of a chronic inflammatory condition of the skin in the right parotid region of eight months' duration. There was nothing to note in his history. He formerly had to do with the buying and selling of horses. The affection began with pain and swelling of the posterior part of the right cheek. Early in August, 1900, and again six weeks later, abscesses were opened below the right ear, and since that time slight discharge had frequently occurred from small openings in the skin. There was now a patch of indurated and congested skin over the right parotid gland, which also seemed involved in the induration. The mouth could not be freely opened, but the jaws and the cavity of the mouth appeared to be healthy. At the time of the first examination there was a small sinus in the skin, from which a drop of pus was expressed which contained yellow grains, presenting under the microscope the characteristic appearances of the ray fungus. The surface of the skin in the affected area was rendered slightly irregular by the healing of numerous small openings from which pus had from time to time been discharged.

Dr. SIDNEY PHILLIPS showed a case of Acute Bronchocele. The patient was a man, aged 18 years, who had always been in good health till Christmas, 1900. He had a cold in January, 1901, but continued work. A small boil came on the right side of the face which was poulticed, after which it burst and soon healed, but the patient had pain and an enlarged gland behind

the right ear, to which iodine was applied by medical advice on Jan. 23rd. On the 25th he noticed a swelling about the thyroid upon the right side which had extended to the left side. About the same time he became breathless and his voice had altered during the last 14 days. There was now very great enlargement of the thyroid gland; both the lobes and the isthmus and a hard outlying nodule could be felt at the lower part of the left lobe; no thrill and no pulsation of vessels in the thyroid could be felt, but there was transmitted pulsation of the carotid artery, especially on the left side. The temperature was 100° F., and the pulse was from 90 to 160 per minute. There was a slight systolic (? hæmic) murmur at the apex. He had not noticed that his eyes had become prominent.—Dr. EWART regarded it as a typical case of thyroidism, and he referred to a case of a young man who was admitted into hospital on account of an aortic regurgitant murmur, and to whom he had given iodide of potassium with salicylate of soda and a little free iodine. A few days later well-marked symptoms of Graves's disease, in the bradycardiac form, developed. In such cases the cacodylate treatment was of benefit.—Dr. R. L. BOWLES related the case of a strong healthy man, who after a swim, during which he sustained a great fright, had sudden and considerable enlargement of the thyroid, so much so that he could not button his collar by two inches. He had heard from him some months later, when the patient stated that the swelling was rather smaller.—Dr. BEZLY THORNE had seen two sisters and their father, all of whom suffered from a similar condition. One patient, aged 18 years, had a high tension pulse and foul breath. He had treated the patient for gastro-intestinal auto-intoxication. He did not think that nerve-shock was an etiological factor.—Dr. PERCY KIDD recalled a case of acute bronchocele in an epileptic subject who had died from asphyxia caused by the enlarged thyroid.—The PRESIDENT asked if any cardio-vascular change had been observed. There was no thrill over the gland, as would probably have been present had the condition been Graves's disease.—Dr. PHILLIPS, in reply, said that he had shown the case on account of its acuteness, though the condition was one which was well known. He had suggested Graves's disease on account of the dyspnœa which did not seem to be due to the pressure.

Dr. PHILLIPS also showed a case of Tachycardia (? Graves's Disease). The patient, a man, aged 28 years, at the beginning of November felt tightness across the chest. Soon after the legs and feet swelled. On admission the pulse was 150 and very feeble, and there were œdema of the legs and much breathlessness that he could not walk many yards. Since then the heart-beat had become stronger, with evidences of dilatation and hypertrophy; the pulse-rate, which had persisted at from 140 to 160, with occasional temporary drops to 110 a minute, was extremely feeble, and was uninfluenced by digitalis or strophanthus or rest in bed. There was slight fulness of the right lobe of the thyroid, but no albuminuria, epistaxis, tremor, or proptosis; there was occasional slight pyrexia.—Dr. DE HAVILLAND HALL said that in his experience one of the commonest causes of tachycardia was influenza. Some of the worst cases that he had seen had been in medical men who had worked through their illness. He had found arsenic of more service than digitalis or strophanthus.—Dr. EWART attached importance to the increase of prevascular dulness which pointed to enlargement of the thymus.—The PRESIDENT said that the future history of the case would be of interest.—Dr. PHILLIPS, in reply, said that the hypertrophy and dilatation of the heart rather favoured Graves's disease. He had tried prolonged rest in bed and strychnine.

Mr. R. J. GODLEE showed a case of Injury to the Left Optic Nerve. The patient was a young man who had sustained an injury to the left side of the head from a fall from a bicycle. This was followed by paresis of the right side of the face and the right upper and lower extremities, deafness of the left ear, and blindness of the left eye. The paresis of the face and limbs had since much improved. The deafness was much less and probably depended upon injury to the tympanum. The blindness continued. There was evidence of injury to the optic nerve—i.e., optic atrophy and the pupil not reacting to light on direct stimulation but acting briskly when stimulation was applied to the right eye.

Dr. KIDD showed a case of Congenital Morbus Cordis and Pulmonary Regurgitation, in a woman, aged 21 years. There was slight cyanosis, especially of the conjunctiva, but no clubbing. The heart was enlarged on the right and left sides. There was a faint diastolic thrill in the second left space. The second sound was everywhere very loud, its maximum intensity being at the third left cartilage. At this point a short diastolic murmur following the second sound was audible at times. The first sound was everywhere feeble and generally doubled. The patient had had attacks of cardiac pain from childhood and had suffered from dyspnœa for three years, but there was no history of rheumatism, scarlet fever, or chorea.

Mr. R. P. ROWLANDS showed a Primary Chancre on the Skin of the Side in a single man, a brewer's drayman, aged 28 years. The sore on the side appeared five weeks ago. A papulo-squamous rash and sore-throat appeared a week ago. The sore was now as large as a half-crown, indurated, and discharging a thin serum. There were hard shotty glands in the left axilla and groin. There was a papular sore-throat. The patient had improved under treatment with mercury. There was no history of contagion. He leaned on his dickey at this spot and this might have determined the site of the sore.—Mr. CAMPBELL WILLIAMS mentioned that the sore had this in common with most extra-genital venereal sores that it was wanting in the usual characteristics of a chancre. He had a rule that if a sore did not yield to simple treatment at once to suspect syphilis.

Mr. W. G. SPENCER showed a case of Bullet-wound of the Brain in a man who had been shot with a revolver, the bullet entering immediately below the centre of the right lower eyelid. The patient was admitted to St. Bartholomew's Hospital with right hemiparesis and aphasia. After being for a time unconscious he recovered. At present there was rigidity of the arm with tremors, which began in March, 1900 (the wound having been inflicted in October, 1899). He had never had any fits. The right lower face was paretic with spasm, the upper face being normal. Sensation in the right arm was good, but there was pain in the muscles and in the middle finger. The muscles were not wasted but voluntary movements were absent except for slight advancement of the arm. Mr. Spencer produced skiagrams showing the situation of the bullet, which was in the region of the posterior clinoid process on the left side. The special senses were not affected and speech was fairly good.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Discussion on the Epidemiology of Scarlet Fever in Relation to the Utility of Isolation.

A MEETING of this society was held on Feb. 15th, Dr. P. MANSON, C.M.G., F.R.S., the President, being in the chair.

Dr. A. NEWSHOLME read a paper on the Epidemiology of Scarlet Fever in Relation to the Utility of Isolation. He admitted that the problem was, in the present state of their knowledge, insoluble, but its discussion would serve to indicate the proper lines of inquiry and of safety in practice. Though the micro-organism of scarlet fever had not been certainly identified there could be no doubt as to its existence; it was killed by heat and disinfectants and the disease was communicable by personal intercourse, by fomites, and by such vehicles as milk. Until, therefore, they knew more of its natural history it was obviously their duty to combat it by the only means at present available—disinfection of things and isolation of persons. A notable feature of the disease was the regular cyclical succession of increasing and decreasing prevalence and mortality, which, however, did not coincide in different towns, which made it necessary to compare only years of maximum with maximum and minimum prevalence or mortality to which, since notification had been practised, they could often add fatality. But there had been in this country a remarkable reduction in the mortality since 1883, which from 1859 has never sunk below 0·28 per 1000 population except in 1873, the year following a period of excessive mortality, when it was 0·19, while since 1884 the highest mortality had been 0·36, and the minimum 0·08. This change, though coincident in point of time with the introduction of isolation hospitals, could not be ascribed wholly to their influence, for it had been observed in towns and even in countries where such isolation had never been attempted, yet it was by no means universal, as had been alleged by the opponents of isolation

hospitals, for while in Berlin the improvements had been very marked there was none in Prague, and little, if any, in Christiania, the only difference being that the oscillations were not so wide as formerly, and the same was the case at Boston. The occurrence of extremely high death-rates followed by others as low, and due to the exhaustion of susceptible material, was characteristic of towns where such isolation was not practised. It was remarkable that the mortality from scarlet fever had always been low in Paris, though that from diphtheria was higher than in any other town in Western Europe, and in Boston, U.S.A., where diphtheria was even more rife; the years of highest mortality from the one disease coincided with those of the lowest from the other. This might suggest a complementary relation between diphtheria and scarlet fever were it not that no such alternation was observed in Berlin, Montreal (where both were very prevalent), and elsewhere. The reduction in the mortality from scarlet fever could not be wholly explained by the improvement that had taken place in the sanitary and social conditions of the people in most civilised countries, for it was not so general, but comparing communities that had adopted isolation with those under equally good sanitary conditions they could not but conclude that it had the effect of moderating the severity of successive cyclical epidemics, and by enabling susceptible individuals to escape infection, if only for a few years longer, it tended to lower the fatality, which was notoriously higher in early childhood. It would, however, be rash to assume that the present reduction of the prevalence, mortality, and fatality which in some towns was now less than 1 per cent. among hospital cases, in other words the attenuation of the virus, would be permanent, for in the early part of the nineteenth century it had been observed, though not to the same extent, and ascribed by Dr. Graves to the depletory treatment then in vogue until the return of the disease to its former virulence disillusioned him, and even now one occasionally, though rarely, met with cases of a malignant type; but that these were in any way connected with the aggregation of patients in hospital was an assumption for which there was not an iota of evidence. In most houses isolation was impracticable and the removal of the patient was necessary to prevent the whole of the susceptible children from contracting the disease. To determine the extent to which hospitals tended to check the spread of the disease he had been collecting statistics, too few as yet for positive conclusion, but sufficient to indicate the lines on which such investigations should be conducted. Taking a number of houses (1) from which the first case had been removed so soon as notified; or (2) not until secondary cases had appeared; and (3) where the patients were treated at home, he noted and tabulated the number of subsidiary cases in each class, the period that had elapsed between the onset of each and of that immediately preceding, as well as since its removal, the number of persons in the same families and in other families occupying the same houses under and over 20 years of age who escaped, with the attack rate for each during the rise and decline of an epidemic, and other data, all of which were greatly in favour of hospital treatment in their crude state, while every proper correction or revision made them more so—e.g., most of the cases treated at home were so because there was ample room for isolation without removal, or because there were no other children in the house to whom the disease could spread; and, on the other hand, secondary cases appearing later than a week after the removal and before the return of the first could not be due to personal infection from it, and in many the patient was not removed until too late for prevention, some, indeed, not until the second or third weeks. As to the alleged higher mortality among "return" cases, even when properly so called, it was a well-known feature of disease that successive cases in a family progressed in virulence, especially when treated at home.

Mr. SHIRLEY MURPHY defended isolation hospitals as removing one means of communication, though others remained to be discovered; statistical results from comparison of isolating and non-isolating towns, apparently against the former, must be falsified by errors of method or ignoring different circumstances, as well as cyclical variations of prevalence and mortality. In 1893, when from the seventeenth to the twentieth week the Metropolitan Asylums Board failed to meet the demand and many patients were treated at home, the number of secondary cases rose rapidly.

Dr. FRANKLIN PARSONS pointed out that it was but recently that hospital isolation had been at all generally adopted, yet the mortality from the isolated diseases had sunk far more than that from measles and others that were not, and it was evident that the aggregation of cases and concentration of the infection was greater in a confined room than in a hospital ward.

Dr. BOOBBYER said that with regard to the comparison of the scarlet fever statistics of different towns variously circumstanced in respect of hospital isolation, he wished to point out that not only were the internal conditions of these towns and the periodicity of their cyclical and local epidemic waves extremely various, but the conditions of their surrounding districts as regards all these matters were at least equally diverse. In many such districts, too, practically no precautions against the spread of infection were taken by the local authorities. Moreover, while very many of these peripheral districts were doing nothing in the way of hospital isolation, the large towns themselves were not doing anything like the amount they were supposed to be doing. For example, the huge discrepancy between the hospital death-rate of Huddersfield during 1899 (1·5 per cent.) and the home death-rate (28·5 per cent.) probably meant, *inter alia*, that more than nine-tenths of the home cases were not notified. With reference to return and other secondary cases he had, he thought, pointed out as far back as in 1892 that these were apparently more fatal than primary cases. Return cases were ordinarily most numerous in autumn, but with a rising epidemic they were most prevalent on the upward slope of the epidemic wave irrespective of season. The low death-rates in hospitals disproved the theory that they gave rise to a new and more fatal type of infection. Still, isolation hospitals had not done as much as was expected of them, and probably the explanation was to be found rather in the life-history of the scarlatinal virus than in faults of the hospitals. Who could say that what was known as scarlet fever was anything more than the outcome of one phase—or incident—of the life-history of an organism whose other incarnations, as saprophyte or parasite, they were unable to follow?

Dr. LOUIS PARKES pointed out the economic advantages of hospital isolation in enabling the parents and others to follow their usual employments, and suggested that the possible presence of the microbe in apparently healthy throats might be a source of infection, as it was in the case of diphtheria, that notification and isolation could not prevent.

Dr. H. R. KENWOOD considered hospital isolation indispensable for the poor, and protested against the indiscriminate admission of patients of all classes to the exclusion virtually, if not actually, of those suffering from far more fatal diseases. In his district of Finchley the children of the poor died from diphtheria while the beds in the hospital were filled with scarlet fever cases, some coming from houses rented at £100 per annum. Half the expenditure of the Metropolitan Asylums Board thus spent might to much better purpose be devoted to the medical inspection of schools and other uses. Even measles was at the present time more fatal, indeed he had several hundred cases of scarlet fever through his hospital in the course of eight years without a single death.

Dr. E. F. WILLOUGHBY expressed his regret that no reference had been made to the age constitution of the populations of the towns under consideration. For scarlet fever being a disease of early life, and rarely fatal after the tenth year, the mortality of a town must be greatly influenced by the number of children living under 10 years. To take an extreme case, children under this age constituted 24 per cent. of the total populations of London and Berlin, but only 12 per cent. of that of Paris, so that equal death-rates per 1000 population would indicate a mortality in Paris twice as much as in London or Berlin among those who were susceptible and to whom the mortality was practically confined.

Dr. H. T. BULSTRODE, referring to Dr. Kenwood's observations as to the expediency of providing isolation accommodation for diseases other than scarlet fever, remarked that obviously if the fatality rate of scarlet fever became much further reduced it might be a serious question as to whether some other infectious disease having a higher fatality-rate might not be attacked. He thought that much of the misunderstanding which obtained as to the value of isolation hospitals arose from a perpetuation of the old view that a disease such as scarlet fever could be "stamped out." But

such a stamping out assumed that the micro-organism of the disease in question was confined to the human species, and that, moreover, it had no saprophytic existence. There was some evidence to negative both these views. But even if the disease was confined to the human species it would be necessary in order to stamp it out to recognise a case the moment it appeared, to isolate it at that moment, and to disinfect all articles which had been exposed to infection at that instant. But all these things were clearly impracticable. The proper attitude to adopt in relation to the present controversy was, he thought, to improve their fever hospitals, to control in a greater degree than at present the diagnosis, to provide more observation wards, and generally to make for better accommodation. The statistics of many isolation hospitals bore witness to the fact that there was some room for improvement, and he thought it wise in every particular to face the situation. All recent experience fully justified the attitude of successive medical officers of the Local Government Board in setting themselves to oppose the erection of unsuitable "temporary" hospitals. Sanitary authorities had no right to morally compel the people under their charge to be sent to hospitals which were not properly equipped.

After some remarks by Dr. R. D. SWEETING, Dr. W. A. BOND, and Dr. THEODORE THOMSON, the PRESIDENT defended what Dr. Kenwood had called indiscriminate admission on the ground of the difficulty of drawing a line of eligibility, since a man's occupation was of more importance to the public than his income. He had sent his children to a hospital in the interest of his practice and patients. The suggestion of a parasitic phase of scarlet fever in other animals was favoured by its remarkable limitation to temperate climates, for it was a character common to all diseases of that nature to be restricted to particular climates or regions

Dr. NEWSHOLME said that Dr. Millard's error consisted not in the shortness of the period on which his statistics were based, but in his method of applying them, which ignored the different incidence of the maxima of prevalence and of mortality in different towns. He maintained that all ratepayers had a right to hospital treatment, which he believed was always better; but if any selection of cases were made it should be made, not on the social position of the families, but on the risk of the spread of infection in each case. He entirely agreed with the importance of taking the age constitution of a population into consideration in comparing one town with another, but had not as yet been able to obtain the information desired by Dr. Willoughby. He thought that Dr. Kenwood's remarkably low mortality might be due to his indiscriminate admission of cases and that its limitation would lead to a recrudescence of the fatality in future.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—The Surgical Treatment of Prolapse of the Uterus.—The President's Inaugural Address.

A MEETING of this society was held on Feb. 14th, Dr. J. A. MANSELL MOULLIN, the President, being in the chair.

Dr. R. D. PUREFOY (Master of the Rotunda Lying-in Hospital, Dublin) showed two very interesting specimens of Fibroid Disease of the Uterus. In the first case a single woman, aged 52 years, was attacked with a severe form of peritonitis for six weeks, and while under treatment was found to have a large, firm abdominal tumour having many of the characters of fibroma uteri. She was sent to the Rotunda Hospital for operation and during this the abdominal wall was found to be firmly incorporated with the anterior surface of a large fibroid connected with the left cornu of the uterus by a small pedicle. The omental adhesions were so numerous and extensive that considerable bleeding ensued during their separation. It was observed that the surface of the tumour presented very much the appearance of an ovarian cyst in which suppuration had occurred. On section the substance of the tumour (except a small portion near the pedicle) was found to be of a dark red colour, and was hollowed out into large cavities freely communicating and containing unaltered blood in large quantities. Dr. H. C. Earl reported as follows on the microscopical appearances: "The tissues of the tumour, though so unusual in colour, did not show degenerative changes, but stained in the usual way, and the numerous cavities having a very smooth lining membrane appeared to be dilated blood-vessels." This condition in a fibroma was of great rarity and very few instances of it had as yet been reported in any country. In the second case the patient was a single woman from whom a large fibroid uterus had been removed by panhysterectomy. The specimen was interesting because it showed numerous submucous, interstitial, and subperitoneal fibroids in various stages of development. The existence of fibroid disease had been recognised six years previously, but it was then in such an early stage and the uterus was so small that no treatment was deemed necessary, and her advanced age encouraged the hope that any further growth would be very slow. In both cases a very satisfactory convalescence followed the removal of the tumours.

Mr. CHRISTOPHER MARTIN (Birmingham) showed three specimens of Mal-formed Uteri. The first was a so-called "double uterus" (didelphys uterus). In this case the left half was patent and the right was distended with decomposing menstrual blood (pyometra). This was first drained per vaginam in May, 1895, but the opening made closed, and retention of the menses with septic complications again supervened. As the patient was becoming pyæmic the double uterus was removed by vaginal hysterectomy in August, 1900. The two uteri were quite distinct, the peritoneum dipping down between the fundi as far as the internal os. The cervical canals were connected by fibrous and muscular tissue, but the two cavities were separate. The patient, who was married and had one child, was 41 years of age. The second specimen was a one-horned uterus. This patient, aged 45 years, had had two children. In May, 1899, Mr. Martin removed a big semi-gangrenous cystoma of the left ovary with a twisted pedicle. When operating he observed that the right ovary, tube, and horn of the uterus were absent. The patient continued to suffer severe pelvic pain with irregular hæmorrhages which nothing benefited. Finally, in September, 1900, Mr. Martin removed the uterus per vaginam with complete relief to the patient's sufferings. The third specimen was a rudimentary double uterus with misplaced hypertrophied ovaries, removed from a single girl, aged 18 years. She had never menstruated and the vagina was a cul-de-sac only one inch long. The external genitals, pubic hair, and breasts were well developed. Each ovary was sausage-shaped, between four and five inches long, stretching from the internal abdominal ring to the corresponding kidney. There were ripening follicles in each ovary. From each ovary there stretched a thin rounded muscular cord, about one-third of an inch thick and three inches long, which dipped down into the pelvis between the bladder and rectum and ended, without uniting with its fellow, in the top of the rudimentary vagina. Evidently here the two ducts of Müller had been arrested in development at a very early stage. All three patients made a complete recovery.

Mr. BOWREMAN JESSETT read a paper upon the Surgical Treatment of Prolapse of the Uterus.

The PRESIDENT delivered his Inaugural Address. The present year, he said, inevitably constituted a historical landmark; but a detailed comparison of modern gynæcology with that which prevailed even 17 years ago, when the society was founded, would have committed him to writing a complete treatise upon the subject. He would limit his observations to a few operations. Asepsis in abdominal surgery not only reduced the mortality following operative procedures, but by making actual inspection practicable when the diagnosis was uncertain rendered early treatment possible. 17 years ago ovariotomy statistics were engrossing attention, and the cleanliness insured by Listerism, as it was then called, was reducing a terrible mortality almost to vanishing point. The success which attended ovariotomy for cystoma led to the removal of the tubes and ovaries for inflammatory affections, and also for the effect which their removal exercised upon fibroid growths of the uterus. In chronic inflammatory disease of the uterine appendages the value of operative treatment was now beyond dispute, and the inefficiency of other forms of treatment had long been recognised. Once the tubes were affected they never regained their healthy condition but remained an ever-possible source of fresh inflammatory trouble. The patients were invariably chronic sufferers and operation alone could give permanent relief. When operation became the recognised treatment whole chapters devoted to earlier methods were practically deleted. Removal of the ovaries for fibroid tumours of the uterus, however, had not fulfilled the expectations to which

the success attending early operations gave rise. It was applicable only to tumours of a comparatively small size, and its results both as regards checking the growth and arresting the hæmorrhage were quite unreliable. The position of the ovaries below and behind the uterus rendered the operation frequently difficult or even impossible and it was not less dangerous than removal of the tumour itself. This naturally led to the consideration of hysterectomy. This was at first an operation of appalling mortality. Keith alone obtained fair results. He recorded 38 cases with three deaths. The extra-peritoneal treatment of the stump introduced by Koeberle marked an important advance, but though many operators working upon this principle obtained excellent results the operation was never regarded as an ideal one. Many modifications followed. Panhysterectomy had then a fair trial, but involved necrosis and foul discharges, and was not a commendable operation. At length the plan of ligaturing both the uterine and ovarian arteries removed the principal danger associated with hysterectomy—viz., secondary hæmorrhage—and at present the generally accepted rate of mortality (with experienced operators) was 5 per cent. Even this rate would unquestionably be lowered were it possible to obliterate the traditional teaching that operation should be deferred till life were threatened or existence was unsupportable. A London teacher had recently given 17 as the percentage mortality, but essential factors had been ignored and the result of a computation so made might as well have been 70 as 17. Turning to removal of the uterus for cancer he said that Mr. Jessett had recorded a series of 107 cases with an immediate mortality of under 8 per cent. Where it was desirable to operate and yet be certain that the disease would recur he questioned the advisability of performing complete hysterectomy. In almost every case recurrence took place in the cicatrix and this, if the uterus had been completely removed, lay in direct contact with the bowel, which therefore became soon involved in the cancerous growth. When the disease commenced in the cervix it extended laterally, not to the body, which became involved at a late stage, if ever, and which therefore afforded greater or less protection to the bowels. In conclusion, he summarised the evolution of modern knowledge on ectopic gestation. The practical lesson which had been learned was that, whatever the phase and whatever the stage, there was but one remedy—viz., operation; where, however, the fœtal heart could be detected the question arose whether the operation, always inevitable, should be undertaken at once or deferred for a time.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 21st, Dr. D. B. LEES, the President, being in the chair.

Mr. J. JACKSON CLARKE showed a case of Spastic Paralysis in a boy, aged six years. The spastic condition chiefly affected the muscles of the right thigh and leg and to a less extent the left side. The parents first noticed it when the child was two years of age. At present the foot was in a line with the leg and the muscles had the characteristic "clasp-knife" action. The boy could not wear an ordinary boot on the right foot and the gait was difficult, the boy preferring to crawl. The mental faculties were somewhat impaired. Mr. Clarke intended to elongate both tendons Achillis and on the right side to divide the hamstrings. During the past four years he had treated surgically many cases of the kind and the results, both in the upper and the lower extremities, had been most satisfactory. Careful post-operative treatment was necessary to insure success. Failures were either due to insufficient operative measures or to want of proper instrumental control after operation. Save in cases where great mental deficiency was present the old rule of non-interference was obsolete. Massage was of no lasting benefit before operation.—The PRESIDENT, Dr. A. A. BATHE, and Dr. W. EWART discussed the case.

Mr. CLARKE also showed a girl, aged 16 years, the subject of Congenital Syphilis. For two years he had treated her for gummata rapidly forming over the nasal bones, in the nasal septum, and at the lateral aspect of the skull. Before that she was under a physician for severe syphilitic enlargement of the liver and spleen. The patient was anæmic and stunted. The common stigmata of the disease were absent and there were no absolutely diagnostic symptoms of hereditary syphilis present. Surgically, epiphyseal and joint lesions and weak spines that resisted ordinary anti-rachitic treatment were common evidences of syphilis. In infants the rule was—When in doubt try mercury; if a rapid improvement followed there was no doubt as to the nature of the morbid condition. The present patient, though suffering from late lesions, had greatly benefited from mercury and iodide of potassium.—Dr. EWART referred to similar features as regards hepatic and splenic enlargement, stunting of growth, peripheral gummata, &c., in a male patient of the same age. In his case there had been early keratitis, perforation of the palate, and clubbing of the fingers, but the teeth were quite unaffected.—Mr. CAMPBELL WILLIAMS thought the case was one of acquired syphilis contracted during the early years of life. There was a total absence of all the classical signs of the congenital type in the teeth, eyes, ears, and physiognomy. Moreover, extensive gummatous ulceration with great destruction of the external soft parts of the nose and adjacent tissues, together with isolated and broken-down gummata, were common in the tertiary stage of the acquired disease, but was not the form of tissue attack selected by the tertiary stage of the congenital type of the malady. Text-books did not recognise that congenital syphilis had its secondary and tertiary stages, just as the acquired form had.—Dr. TRAVERS SMITH and the PRESIDENT also took part in the discussion, and Mr. CLARKE replied.

Dr. EWART and Mr. S. VERE PEARSON showed a case of Phthisis treated by Maguire's Formaldehyde Injections. The patient was a male, aged 28 years, in whom bilateral apical tuberculous infiltration without the major signs of excavation was complicated by dental and dyspeptic trouble. Although not a pure instance of the treatment, since other measures had also been adopted, it indicated the partial improvement which might be obtained in a case of marked tuberculosis. After 23 injections of formaldehyde the patient still coughed up numerous bacilli and the râles persisted at both apices, but there was marked general progress in the expansion and resonance of the chest on percussion. The cough was better and the expectoration was less and had changed from muco-pus to clear mucus. A second course was contemplated after a stay in the country.—The PRESIDENT requested Dr. Ewart to favour the society with the general results, as far as he could state them, which he had obtained from this plan of treatment. It was necessary to be very cautious in drawing conclusions from individual cases. The importance of very carefully weighing the evidence for and against a new treatment of this kind was indicated by the past experience of the profession with regard to tuberculosis.—Dr. DUTCH, Dr. BATHE, Dr. E. CAUTLEY, and Mr. HUBERT PHILLIPS also discussed the treatment.—Dr. EWART, in reply, stated that his experience of the treatment was decidedly favourable and agreed with that of Dr. Maguire. He referred to other cases shown elsewhere in which the good results had been manifest. In view of the careful manipulation necessary and of the slight complications apt to arise, such as local swelling, thrombosis, &c., he could not recommend the treatment for out-patients. In hospital and private practice he had not had any serious complications and no abscesses.

Dr. BATHE showed a boy, aged 11 years, who was subject to recurrent attacks of Psoriasis Guttata for three years and he asked for suggestions as to methods for preventing the attacks.—Mr. WILLIAMS and Dr. SMITH discussed the case and made some suggestions as to treatment and prognosis.

Mr. H. J. CURTIS showed an infant with Accessory Auricles on the Neck.

Dr. W. J. HARRIS showed a typical case of Brachial Neuritis which was associated with loss of radial pulse on the same side.—The PRESIDENT said that he could entirely confirm what Dr. Harris had stated as to the improvement in this case. Brachial neuritis or neuralgia certainly occurred as a sequela of influenza, but not usually with such marked symptoms, and it seemed possible in this case from the history, the absence of the radial pulse, and the fact of a dilated left ventricle, that there had also been embolism or thrombosis.—Dr. HARRIS demonstrated a method of applying a combination of the galvanic and faradaic currents in the treatment of the case and the meeting then adjourned.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Psychoses following Pelvi-abdominal Operations.—Apparent Low Implantation of the Ureteric Opening.

A MEETING of this society was held on Feb. 13th, Dr. R. MILNE MURRAY, the President, being in the chair.

Dr. F. W. N. HAULTAIN showed a Large Œdematous Fibroid removed by Abdominal Hysterectomy and Double Dermoid Ovarian Tumours, one being associated with Supernumerary Ostium of the Fallopian Tube.

Dr. N. T. BREWIS showed a Uterus with Cancer of the Body; a Fibroid Uterus studded with Tuberculous Nodules; and two other Fibroids removed by Hysterectomy.

Dr. MICHAEL DEWAR showed two Hodge Pessaries which in three months had become almost circular and unbent while in the vagina. No hot douche had been used by the patient, and in order to soften them it required a much higher temperature than could be borne by the vagina. The explanation might lie in inferior manufacture due to the scarcity of rubber.

Dr. J. HAIG FERGUSON exhibited a Photograph showing Displacement of the Sigmoid Flexure of the Colon in front of a Full-time Pregnant Uterus; and a Cystic Kidney removed by Abdominal Section, which lay in the pelvis and presented some of the physical signs of an ovarian cystoma.

Professor A. R. SIMPSON showed an Ovarian Fibroma; a Double Ovarian Carcinoma from a patient, aged 26 years; and a Double Ovarian Cystoma (one had ruptured) and a Tubal Pregnancy.

Dr. G. KEPPIE PATERSON showed a specimen of Hydramnios of the Ovum. It was expelled at between two and a half and three months after cessation of the menses and was of about the size of a lemon of moderate dimensions. The amnion with its contents was expelled alone and whole, the decidua following a few days afterwards. The fœtus was found attached to the amnion and was evidently of less than three weeks' growth, so that the amnion must have continued secreting the liquor after the death of the fœtus. At six weeks after cessation of the menses no appreciable enlargement of the uterus could be detected. The patient suffered more than ordinarily from the vomiting of pregnancy.

Dr. J. HALLIDAY CROOM read a paper on Psychoses following Pelvi-abdominal Operations. Mental aberration occurred after operations in general surgery, even after such a minor accident as a simple fracture. After the administration of anæsthetics delirious mania had followed and in some cases weak-mindedness had lasted for a very variable period. Abdominal and pelvic surgery was no exception. The normal functions of the uterus and ovaries were themselves not unassociated with mental aberrations; alterations in the temper, actual hallucinations, and disordered appetites of all kinds were accompaniments both of menstruation and pregnancy. The same was the case with the menopause: it was more frequently associated with curious mental phenomena than any other period of a woman's life. Everyone was acquainted with the frequency of insanity occurring after ordinary labour, but puerperal insanity generally occurred in those whose personal or family history indicated some mental weakness. Dr. Croom first gave an illustrative case of mental disturbance associated with menstruation in an otherwise healthy woman with a good family history where no operative interference had been carried out. The patient was unmarried, aged 26 years, and the complaint was that for 10 years she had exhibited symptoms of violent dislike to her relatives, especially her brothers and sisters, during the five days that her catamenia lasted. She was morose during all the period, declined to speak to any member of the family, and was violently insulting when spoken to, but the day after the catamenia ceased she was bright, cheerful, and desirous of enjoying all the pleasures of life. She had been examined under chloroform and nothing morbid was found. She had no dysmenorrhœa. Her sisters were all healthy and well and there was no history of insanity in the family as far as could be ascertained. She married and shortly afterwards became pregnant, and during the whole of the pregnancy she exhibited symptoms similar to those occurring during menstruation. Shortly after labour she became perfectly well and had remained well since, even during her menstruation. Of insanity occurring after operation Dr. Croom instanced the case of a young widow, aged 32 years, who was suffering from villous endometritis with profuse hæmorrhage, both menstrual and inter-menstrual. She was curetted and made an excellent recovery. Some weeks afterwards she took an inordinate dislike to her child, threatened to murder it, and she is now an inmate of an asylum. Another was a young woman, aged 25 years, reduced to a state of extreme anæmia from constant and profuse uterine hæmorrhage dependent upon the presence of a uterine polypus. It was of about the size of a hen's egg. Such an operation entailed no very great shock to the system. The patient left the nursing home perfectly well and there had been no return of the hæmorrhage. Two months afterwards she harboured the delusion that she had been delivered of a child and was now in an asylum. So far as could be discovered there was no family history of insanity either direct or among her relatives. It might be possible to account for this case by the fact of the profound anæmia of the patient, and under such circumstances the shock of the operation would be comparatively great; but then the symptoms did not appear for at least two months after the operation, and by that time she had become physically stronger in every way. The nature of her delusion indicated that her insanity was associated with the operation and not an accidental coincidence. These cases indicated that such accidents might occur after gynæcological operations and unfortunately were utterly and absolutely unpreventable. Another case was that of a young woman of an exceedingly healthy family who suffered from intense spasmodic dysmenorrhœa which withdrew her from active duties every month. After consultation with her friends the cervix was dilated and for the two succeeding months she was quite free from dysmenorrhœa, but at the third month she became violently maniacal, and her mental equilibrium had been so very much upset ever since that her marriage had to be abandoned. Dr. Croom could also give cases of mental changes following minor operations, though fortunately less pronounced and attended with happier results than those just cited. Kelly recorded six cases of insanity after perineal operations, and one of these patients died in acute mania. Major operations might also be followed by mental disease. A patient, apparently in robust health, was operated on for a simple ovarian tumour. There were no adhesions and no difficulty whatever in the operation, which lasted 10 minutes. On the following day the patient became maniacal and she died from exhaustion in four days. It might probably be said that this was the mania or delirium of sepsis but the necropsy showed not a trace of sepsis anywhere. There was no family history of insanity. Kelly on this subject recorded eight cases out of over 2000 abdominal sections; of these five patients recovered, two remained insane, and one committed suicide. Dr. Croom's record showed five cases of insanity in over 1000 sections. Another case occurred after a rather troublesome ovariotomy with numerous adhesions. The patient made an excellent recovery. On the seventh day the stitches were removed and the wound had completely healed except for one stitch tract suppurating. On the same evening she became excited, and two days later acutely maniacal. She died shortly afterwards. One of the most painful cases was that of a patient who had hysterectomy performed for a rapidly-growing fibroid. The tumour was a large one involving a wound nearly from the ensiform cartilage to the pubes. The stump was treated intra-peritoneally. All went well till the night of the seventh day after the stitches had been removed. In the very short absence of the nurse the patient jumped out of bed, tore off the dressing, and before she could be brought back to bed the strapping had given way. This allowed the wound to reopen at its lower margin and a small portion of the gut escaped. She was in a state of violent excitement and was anæsthetised with difficulty. The temporary hernia was dealt with and the patient recovered, but only to become an inmate of an asylum, where she still was. The next case was one of melancholia which supervened six months after a simple ovariotomy. It was an easy operation and the recovery was good, but six months later the patient began to show symptoms of dislike of her friends along with evidence of suspicion and melancholy. She had now been some time in an asylum. In all the cases the operation in itself was entirely successful, and, as far as could be traced, they had no hereditary tendency whatever in any direction. In looking for causes of these mental disturbances after operation the first factor was the hereditary one and the second

possibility was sepsis; loss of blood, defective action of the kidney, &c., had also their influence in producing mental symptoms. In removing the ovaries the climacteric was induced and the woman was placed in all the possible risks of that period. Probably a neurotic constitution was an essential pre-requisite for the development of post-operative insanity. In all the cases narrated the possibilities of sepsis were excluded by careful precautions. Alienists said that the main element in the production of post-operative insanity was a predisposition, hereditary or acquired. It was remarkable that it had not been shown that insanity was more common after operations on the genital organs than after operations on any other organ, yet mental troubles were often associated with the normal occurrence of puberty, menstruation, pregnancy, and the menopause. The subject of operations undertaken in insane women with the view of effecting a cure of the mental disease was also touched upon. Dr. Croom considered that under no circumstances ought any insane woman to be operated upon unless for some distinct condition which was compromising life. Removal of ovaries and other operations performed with a view of influencing insanity or hysteria were exceedingly discouraging. He had removed the ovaries in a case of hystero-epilepsy with evident cure of the nerve symptoms. It was quite certain that after degenerative processes had occurred in the brain cells it was absolutely useless to look for any mental cure by any form of operative procedure.—Professor SIMPSON, Dr. D. BERRY HART, Dr. HAULTAIN, Dr. J. W. BALLANTYNE, Dr. A. ROBERTSON, Dr. JAMES RITCHIE, Dr. BREWIS, and the PRESIDENT discussed the paper.

Dr. BERRY HART read a paper on Apparent Low Implantation of the Ureteric Opening. Several cases of incontinence of urine had been recorded where the cause was an apparent low implantation of the end of the ureter on the vestibule near the edge of the urethra or the hymen and on one side usually. Cases had been narrated by Baker, Davenport, von Massari, Benckiser, Sänger, and Olshausen. Difference of opinion had existed as to whether the whole tube was ureteric or only its upper part ureteric and its lower part Wolffian. Dr. Hart discussed the anatomy and development of the Wolffian duct and ureter and advocated the opinion that the whole aberrant tube was not ureter but ureter in the upper part and Wolffian duct below. The anomaly was due to the persistence and potency of the lower segment of the duct and to its original junction with the ureter. The operation necessary in such cases was briefly described.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Psammoma of the Optic Nerve.—Exhibition of Specimens.

A MEETING of this section was held on Jan. 11th, Professor A. C. O'SULLIVAN, the President, being in the chair.

Mr. SWANZY and Dr. H. C. EARL described a case of Psammoma of the Optic Nerve. Mr. Swanzy had removed a tumour of the optic nerve by Knapp's method, leaving the eyeball intact in the orbit. The tumour measured one and a half inches long by three-quarters of an inch wide. It filled the orbit and had caused very marked proptosis of the eyeball. The eye was blind from optic atrophy. The microscopic examination by Dr. Earl showed the following structure of the tumour. The cellular elements of the tumour were principally small, round, mononuclear cells. There was very little fibrous connective tissue present. The fibres of the optic nerve could be traced through and over the surface of the tumour, which lay within the dural sheath of the nerve, except at its posterior part. There were numerous calcified rounded bodies of varying size, all showing more or less distinct lamination. Blood-vessels were numerous in some parts, and these were the parts which contained fewest calcified bodies. There were found also numerous masses of a hyaline material which contained generally a few round cells. The most usual tumour of the optic nerve was myxoma or myxo-sarcoma. Mr. Swanzy and Dr. Earl had been unable to find any case of psammoma of the optic nerve on record within the last 16 years, the literature for which period they had searched. Two text-books stated that psammoma of the optic nerve did occur, but gave no reference to cases.—Mr. STORY said that, as far as he knew, it was the very first case in Ireland, perhaps in the United Kingdom, in which a tumour of the optic nerve had been surgically removed with the preservation of the eyeball.—Professor E. J. MCWEENEY said that on looking at the microscopic specimens of the calcareous bodies the impression he got was that they were something in the nature of calcified corpora amylacea. He had often met with corpora amylacea in various parts of the central nervous system almost as large as those he saw to-night, but certainly not so numerous. He had seen appearances precisely similar in the prostate gland except that the individual corpora were larger. Dr. Earl's reference to a preliminary hyaline stage in these masses would seem to bear out the idea that they were of the nature of calcified corpora amylacea, as it was well known that these bodies were at first hyaline before calcareous deposition set in. The term "psammoma" implied, he believed, a laminated concentric arrangement of layers of fibroid tissue surrounding the central masses. This was found in the pineal body, which was the type of psammomata, and in the absence of a definite lamination of the connective tissue round these corpora amylacea he should hesitate to call the structure a psammoma. He only expressed these views in a tentative way, as he had not the opportunity of making more than a cursory inspection of the sections. With regard to the involvement of the optic nerve itself, he confessed that he did not see any nerve fibres in the specimen. If corpora amylacea were really the groundwork of the tumour it was robbed of its rarity to a great extent, as these bodies were found frequently in the nervous system in both normal and pathological specimens.—Mr. SWANZY, in reply, said that in removing the tumour the external rectus was divided (it was not necessary to dislocate the eye forward, as that was already done) and the eyeball turned over on the base of the nose, which happened to have a low bridge; otherwise he would have selected the internal rectus. By these means he could easily get at the optic nerve as it entered the eyeball, and he found the tumour pressed close to the eyeball, without being adherent. He divided the optic nerve with the scissors, which enabled dislocation across the nose to be carried further. He felt round the tumour with his finger and separated it as far as possible, dividing it then with scissors close to the optic foramen. After suturing the external rectus to its stump he replaced the eyeball in its socket. There was now no sensation in the cornea and the retina was beginning to undergo degeneration. He thought it hardly likely that the eye would prove useful as an ornament. The eyelid was drooping now, but on retraction taking place, as he believed it would, he was quite certain that the cornea would slough. He hardly thought it to be an operation suited for a tumour of the optic nerve itself. It was more suited for non-malignant tumours of the orbit, without interfering with the optic nerve, the cutting of which would mean interference with the nutrition of the eyeball. He therefore did not consider it a very useful operation.—Dr. EARL, replying to Professor MCWEENEY, said that the calcified bodies might have been calcified corpora amylacea, but then there were no non-calcified corpora amylacea in the specimen, which he thought was a peculiar coincidence; and, furthermore, the hyaline material, the precursor of the calcified bodies, was not laminated at all.

Dr. TRAVERS SMITH exhibited the Stomach of a Man, aged 45 years, presenting an Enormous Carcinomatous Tumour along the greater curvature projecting into the lumen but sparing the orifices. The patient suffered from neither pain nor vomiting, his appetite was good, and his bowels were regular. The specimen was of interest as illustrating how vast a carcinoma might be present in the stomach without producing stomach symptoms if the growth did not involve the orifices.

Dr. EARL showed the Ovaries of a Child at Birth which contained a large number of Follicular Cysts. The greater part of the ovarian tissue was destroyed by the pressure of the cysts.

Professor MCWEENEY demonstrated Blood Films from a case of Spleno-medullary Leukæmia which he had at present under observation. The condition was quite characteristic, the red corpuscles being 3,440,000 and the white being 300,000 per cubic millimetre. Myelocytes were very numerous, a large minority being eosinophil.

Normoblasts were extremely numerous, each field containing several; megaloblasts were also common.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held on Feb. 14th, Mr. Rutherford Morison, the President, being in the chair.—Dr. E. H. Davis showed a youth, aged 19 years, who after operation for exostosis on the posterior and outer aspect of the humerus 12 months ago developed complete Musculo-spiral Paralysis. Operation was advised with a view to suturing the divided nerve.—Dr. I. G. Modlin showed: 1. A woman, aged 30 years, who after having been treated for other tuberculous bone lesions had the Left Elbow-joint Excised. There had been some local recurrence of tuberculous disease in the elbow a few months later; this time it was treated by scraping, packing with iodoform gauze, and a glycerine emulsion of iodoform. The elbow now showed a perfect result. He cited several cases in which treatment by iodoform emulsion had been successful and claimed for it some specific anti-tuberculous property. A lengthy discussion ensued in which the consensus of opinion was against the specific action of iodoform emulsion. 2. A woman, aged 49 years, whose Right Breast was Removed with the Glands three years ago. There was recurrence a year after and again 18 months later in the axillary glands and finally three months ago. Injections of Coley's fluid, which were begun on Dec. 22nd, were continued daily until Dec. 31st, when they were suspended for three weeks, and then they were given irregularly until Feb. 8th, the dose being gradually increased up till 15 minims. No benefit had resulted.—Many of those present related their experiences with Coley's fluid, thyroid extract, and Chian turpentine in inoperable sarcomata and carcinomata, universally without permanent good result.—Dr. G. R. Murray showed a miner, aged 29 years, who had syphilis five years ago which was treated for one month only. Three months ago he developed frontal headache, alteration of vision, and daily fits during which consciousness was not lost. The fits consisted of giddiness, pricking sensation in the left hand, followed by chronic spasm of the left arm spreading to the leg of the same side. Examination revealed general weakness of the arms and legs, increased reflexes, and difficulty in walking due to post-neuritic atrophy. The treatment, which consisted of iodide of potassium and mercury internally and mercurial inunctions, had resulted in almost complete cessation of the fits.—A lengthy discussion followed in which the following points were considered: mercurial *versus* anti-mercurial treatment of syphilis, imperfect anti-syphilitic treatment predisposing to tertiary lesions, the maximum useful dose of iodide of potassium, and early trephining for the treatment of optic neuritis and the prevention of optic atrophy. The opinion was against operation in this case because of the destructive effects of the lesion and the permanence of optic atrophy and the relief of the symptoms by the present treatment.—Dr. W. G. Richardson showed a case of Ruptured Abscess of the Broad Ligament. The patient, a woman, aged 25 years, had had uterine hæmorrhage two months ago, apparently not abortion. A month ago there was sudden abdominal pain, with faintness, sickness, and collapse, and on the following day when the patient was admitted to the hospital the abdomen was found to be distended and there was dulness in the flanks. The abdomen was opened. The peritoneum contained pus and in the left broad ligament was a swelling containing pus which was removed with ovary and tube. Friability of the tissues prevented ligature and necessitated the fixing of the left cornu in the lower end of the incision. The peritoneum was washed out and a drain was left in Douglas's pouch. In spite of extreme collapse and rupture of the abscess into the general peritoneal cavity a good recovery had been obtained. The primary focus of infection could not be found, the removed ovary and tube being healthy.—Dr. A. M. Martin showed a youth, aged 19 years, whose shoulder had been crushed five weeks ago. He had been treated by a bone-setter previously to the operation. The movements of the shoulder-joint were restricted and painful. Physical signs pointed to fracture and sub-coracoid dislocation of the head of the humerus. Operation by anterior incision was performed. The fractured head was found in the glenoid fossa and was excised, the deformity having been entirely due to displacement of the upper end of the lower fragment. The result of operation showed great improvement in mobility.—Dr. G. G. Turner showed a case of Charcot's Elbow. A man, aged 49 years, fell upon his wrist two and a half months ago, injuring his elbow, which became swollen and painful. In a few days he recovered sufficiently to resume work; five days later the elbow began again to swell. The patient now exhibited enormous swelling, increased flail-like mobility, and large osteophytic outgrowths. On account of this development he was discovered to have Argyll-Robertson pupil, absent knee-jerks, and ataxia, which was especially well marked in the arms.

MIDLAND MEDICAL SOCIETY.—The sixth ordinary meeting of this society was held on Feb. 13th at the Birmingham Medical Institute, Mr. Jordan Lloyd, the President, being in the chair.—Dr. O. J. Kauffmann showed a man, aged 22 years, suffering from Friedreich's Ataxia. The patient had ataxia on walking of considerable, though but mild, degree, and showed Romberg's symptom very marked. There was also ataxia of the hands fairly marked on writing. The knee-jerks and plantar reflexes were both absent. There were no sensory symptoms and at no time had the patient suffered from fulminant pains. Fine shaking of the head was present, particularly on an attempt to fix an object, and quick, shock-like nystagmus was marked when the eyes attempted to follow rapidly a moving point. This last sign had developed while the patient was under observation. There was no tremor of the hands, and at no time had the patient had any difficulty of micturition. The fundi oculorum were normal; the intelligence was very good. Symptoms of this illness had first appeared five or six years ago, and had commenced with severe, often intolerable, itching under the balls of the toes. Gradually unsteadiness in walking and standing had crept on, at first only noticeable to the patient himself, but within the last two or three years perceptible to others and compelling him six or eight months ago to give up work. He had been a sufferer from periodical headaches which he connected with his present illness. The family history was inconclusive, the patient having left home at the age of 11 years and not having seen his people since then. Although he had led a varied and hard life he bore no marks of syphilis and strenuously denied ever having suffered from this disease, and showed no signs whatever of intemperance. As regards the diagnosis, the only other disease which might be thought of was insular sclerosis; but the rather early onset and the total absence of the knee-jerks, coupled with the absence of tremor from the hands and arms, were points against the diagnosis of that condition.—Mr. F. Marsh showed a specimen of a Wool Swab which had been encysted in the peritoneal cavity for 17 months and had been removed by him 10 days previously. The patient was a man, aged 51 years. In September, 1899, an exploratory operation had been performed in a hospital on account of symptoms pointing to gall-stones. "Adhesions" only were found. No relief was afforded, and after a few months the intermittent pains became constant, the vomiting more frequent, and the action of the bowels very irregular. He was admitted into the Queen's Hospital in October, 1900, but careful and repeated examinations failed to discover any definite cause of the symptoms. Subsequently he attended as a medical out-patient. A fortnight ago a distinct swelling, hard and rounded, was noticed for the first time, presenting at the lower edge of the liver in the region of the gall-bladder. He was therefore admitted for an exploratory operation, no definite diagnosis being made. On exposure the swelling resembled a thickened and distended gall-bladder, adherent everywhere to coils of intestine and omentum. These adhesions were with difficulty broken down and the coils of intestine freed. An incision was made into the swelling when a little odourless pus escaped from around a sebaceous-looking mass which further examination showed to be wool, about an ordinary handful. The cyst wall was removed in its entirety. No other lesion was found. The man made a good recovery and was now free from pain.—Mr. Christopher Martin showed a large Subserous Myoma which had become strangulated from Axial Rotation on its Pedicle. It was removed from a married woman, aged 40 years. The tumour caused few symptoms till rotation occurred when acute peritonitis set in. When the abdomen was opened the tumour, which was of about the size of a football, was found to be semi-gangrenous, of a greenish black colour, and universally adherent to small and large omentum. The pedicle attached to the fundus was three inches long and twisted through three complete turns.

After separating the adhesions the pedicle was ligatured and the growth was removed. The rest of the uterus was studded with smaller myomata and was accordingly removed by the sub-peritoneal method. The patient made a good recovery and returned home on the seventeenth day.—The President showed a Suppurating Ovarian Dermoid removed by abdominal section from a girl, 18 years of age, who was admitted to the workhouse infirmary with symptoms of puerperal fever coming on a few days after her first confinement. The tumour lay fixed in the left loin and had most of the characters of a renal enlargement.—Dr. W. J. McCardie read a paper on the Choice of an Anæsthetic.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on Feb. 15th at the Paddington-green Children's Hospital, Mr. Watson Cheyne being in the chair.—An Address of Condolence to the Crown, drawn up by the council, was approved by the meeting, the members meanwhile standing.—Dr. Arnold Lawson showed a case of Acute Retro-bulbar Neuritis in a girl, aged 10 years, with a tuberculous personal and family history. The sight of one eye had suddenly failed in May, 1900. The pupil was semi-dilated and almost immobile, and the edges of the optic disc were slightly blurred. Two days after the excision of the other eye (which had been lost in early infancy) there was a remarkable improvement in the sight of the remaining eye. Colour sense was good as regards blue and red, but absent as regards green. The optic disc was atrophied. The pupil acted to light.—Dr. McCaw said that the case reminded him of one of cerebellar tumour with optic neuritis.—Mr. Watson Cheyne showed a case of Coxa Vara in a child, aged 10 years, in which four years ago he had operated upon the left leg in the following manner. A longitudinal incision was made on the outer side of the thigh at the upper part and the femur divided transversely below the lesser trochanter. The limb was then rotated inwards, so that when fastened to the upper part of the femur it moved through the normal limits of rotation. The ends of the bones were fixed in this position by an aluminium plate, which embraced both, and was secured by nickeled tin-tacks. The plate was still in, the position of the foot was normal, and the patient walked quite well with that leg. The other leg was one and a half inches shorter than its fellow and showed marked external rotation. Mr. Watson Cheyne advocated operating on both legs at the same time in other cases.—Mr. Clement Lucas said that the procedure described by Mr. Cheyne was generally known as Gant's operation, though perhaps not used for coxa vara.—Mr. Jackson Clarke and Dr. G. A. Sutherland made some remarks.—Mr. Watson Cheyne, in reply, said that Mr. Gant divided the femur below the trochanter for flexion or for abduction and not for rotation. He thought it would be difficult to get enough rotation from inter-trochanteric osteotomy.—Dr. Leonard Guthrie showed a Myxœdematous boy, aged six years, after six months' treatment by thyroid gland extract, with photographs illustrating the improvement that had taken place.—Dr. Sutherland, Dr. Fletcher Beach, and others discussed the case.—Dr. Dan McKenzie showed an infant, nine months old, affected with head-jerking and nystagmus of about two months' duration. Twitching of the left corner of the mouth and of the shoulder muscles on the same side had been noted. The patient was slightly rickety and very intelligent for her age. Temporary lapses into unconsciousness had been observed. She was improving under small doses of arsenic.—Dr. Edmund Cautley and Dr. Sydney Stephenson discussed the case.—Mr. Jackson Clarke showed a child, aged nine months, who at birth had marked Macrostoma and Severe Club Hand, both on the right side. The former had been successfully operated upon when the child was five weeks old. Later Mr. Clarke contemplated operating for the club hand by section of ligaments, elongation of tendons, and splitting the lower end of the ulna.—The Chairman and Dr. Sutherland offered a few remarks upon the case.—Dr. Lambert Lack showed a case of (?) Basic Meningitis due to acute suppurative otitis in which recovery followed puncture of the drums of the ears.—The Honorary Secretary showed for Dr. George Carpenter a case of Proptosis in a girl, aged 12 years, who presented no other evidence of exophthalmic goitre except the occasional presence of Graefe's sign.—Dr. McCaw read a paper upon a case of Tetanus Neonatorum which had been successfully treated with anti-tetanic serum. The diagnosis was confirmed bacteriologically.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 19th, Mr. F. A. Southam, the President, being in the chair.—Mr. H. Lund showed three cases of Osteal Sarcoma.—Dr. A. Wahltuch showed two patients Treated Successfully by Massage—viz., (1) infantile paralysis in a child, aged four years, and (2) a girl, aged 17 years, who had suffered first from neuralgic headaches, bald patches appearing later near the fontanelles, and subsequently white hair growing to normal length on the affected areas. The normal hair was of a very dark brown colour. The effect of four months' massage was the appearance of a new growth of dark hair replacing the white.—Mr. J. E. Platt gave a demonstration on the Treatment of Flat-foot.—Dr. J. Gray Clegg showed: (1) an Unusual Case of Graves's Disease in a man in which there was marked proptosis of the left eye only and enlargement of the right lobe of the thyroid gland; and (2) a form of Chronic Ulcer of the Cornea.—Mr. J. Howson Ray showed two cases of Traumatic Epilepsy treated by Sub-dural Implantation of Silver Foil. The first patient was a soldier of the Black Watch, aged 30 years, who was wounded in the left parietal region at Magersfontein in December, 1899, when portions of the parietal bone and underlying brain were damaged. He was operated upon in Cape Colony and was then invalided home. Jacksonian epilepsy came on about May, 1900, and a preliminary trephining showed embedded spicule of bone about an inch away from the original wound, as well as adhesion between the dura mater, scar tissue, and damaged cortex. Mr. Ray separated the dura mater from the adherent brain and introduced a piece of silver foil measuring one and three-quarter inches by one inch beneath the dura, to which it was sutured. This operation took place on Oct. 22nd, 1900, and up to the present time two fits only had occurred and there was marked improvement in the general condition. The second patient was a civilian, aged 21 years, who was injured four years previously when about a third of the right parietal bone was smashed and the underlying cortex cerebri was destroyed. Adhesion of the dura mater to the brain supervened, leading to frequent epileptic seizures of the Jacksonian type. Operation was carried out as in Case 1 on Oct. 24th, 1900, when a piece of silver foil measuring two and a quarter inches by one and a half inches was sutured in position. Up to the present no fits had occurred since the operation. A radiogram was exhibited showing the silver foil in position.

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—A meeting of this society was held on Feb. 7th.—Dr. F. C. Coley read a paper on Quacks and their Advertisements. The paper, which was illustrated by pamphlets, cuttings, and instruments, was most interesting and caused great merriment in the meeting. At the beginning Dr. Coley wished to impress the fact that a large amount of responsibility rested on the profession in the matter, and "the judicious pointing out of some of the errors to the public was one way of leaving this dirty world a little cleaner." One way in which this latter might be effected was by approaching the managing authorities of the more respectable periodicals and persuading them to have the more objectionable and harmful advertisements expunged. Quackery was defined as "a pretence of knowledge which was not there, combined with the treatment of a patient with no chance of a diagnosis."—Dr. F. Hawthorn, Dr. T. M. Allison, Dr. Alderson, Mr. Toggin, Dr. J. W. Leech, Dr. S. S. Whillis, and Dr. G. G. Turner discussed the paper and quackery in general.—Dr. Turner read notes on two rare cases of Strangulated Herniæ, the specimens being shown. The first case was that of an elderly man with a strangulated umbilical hernia. The operation for his relief included the insertion of Paul's tubes. Although rallying for 24 hours he sank at the end of the third day from shock. In the second case a woman was operated on for strangulated femoral hernia. Free herniotomy in the usual manner was performed, but Mr. Turner not being satisfied that the obstruction had been relieved opened the abdomen in the linea semilunaris. It was then found that the peritoneal neck of the sac was the cause of the constriction and also that the hernia had been reduced, although constricted, into the sub-peritoneal tissue. Liberation of the gut was effected, but the patient ultimately died from gangrene of the gut at the point of constriction. Mr. Turner laid stress on the constricting structure not being the usual one and on the difficulty of

determining when the bowel was in a safe condition to return.—Dr. Hawthorn, Dr. Leech, and Dr. T. Beattie discussed these two latter points with reference to cases in their experience.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Feb. 1st, Dr. Cresswell Baber, the President, being in the chair.—Dr. J. Donelan showed a case of Nasal Polypi with marked deformity, and also a specimen from a fatal case of Exophthalmic Goitre in which the thymus was not only persistent but actually enlarged. This he pointed out was quite usual in such cases and raised the question as to whether it had any causal relationship to the disease.—Dr. Wyatt Wingrave showed a section of a Mucous Patch of the Tonsil.—Dr. A. Bronner exhibited a New Cutting Trephine for Nasal Operations which he worked with an electro-motor.—Sir Felix Semon showed a drawing of Symmetrical Congenital Gaps in both Anterior Pharyngeal Pillars with Complete Absence of the Tonsils.—Dr. StClair Thomson thought that it could not yet be stated definitely that such cases were of congenital origin.—Dr. Davis showed a case of Cyst of the Floor of the Nose.—Dr. MacBride discussed the causation of such cysts.—Dr. Lambert Lack showed a case of Mucocele of both Frontal Sinuses which had expanded the bones and pushed the eyes outwards. He had opened the sinuses and on the left side had established a free opening into the nose. This side was doing well, but the right side did not make progress. He asked whether any further operation was advisable.—This was discussed by Dr. H. Tilley, Dr MacBride, and the President.—Dr. Lack also showed a case of Persistently Recurring Nasal Polypi with Frontal and Ethmoidal Suppuration on which he had operated with very good results.—The indications for operations on the frontal sinus were discussed by Dr. Tilley, Sir Felix Semon, Dr. FitzGerald Powell, Dr. Lack, and others.—Dr. Tilley showed some Papillomata removed from a child under anæsthesia in the sitting posture.—Dr. Dundas Grant showed a case of Epithelioma of the Tonsil, and a Section of a Vocal Cord which clinically suggested malignant disease, but microscopically proved to be inflammatory.—Dr. Grant, in conjunction with Dr. Mackintosh, also showed a case of Glottic Spasm in a woman, aged 24 years.—Dr. William Hill showed a case of Innocent Growth of the Right Vocal Cord, and Dr. Atwood Thorne and Dr. Dundas Grant with Dr. Wyatt Wingrave, showed Laryngeal Cases for Diagnosis.

LIVERPOOL MEDICAL INSTITUTION.—The third meeting of the Pathological and Microscopical Section of this society for the session 1900–91 was held on Feb. 21st, Dr. J. Hill Abram being in the chair.—Dr. Nathan Raw showed three specimens of Pericarditis, one acute fibrinous, one septic, and another tuberculous. Dr. Raw also showed a rare specimen of Cystine Calculi in a kidney and ureter.—Dr. W. Alexander and Dr. Dimond showed: (1) a specimen illustrating the Infiltration of a Multilocular Ovarian Cystoma from adjacent Malignant Disease of the Sigmoid Flexure; (2) a soft Myxoma removed from the groin of a man, for which he had been operated upon twice previously; and (3) a Fractured Pelvis of severe type, but which had not been accompanied with injury to any of the viscera.—Mr. W. Thelwall Thomas showed: (1) a Carcinoma of the Kidney, 5½ lb. in weight, which had been removed from a patient, aged 50 years, after suffering from hæmaturia for many years; (2) a Rodent Carcinoma removed from the occiput of a man aged 62 years; and (3) specimens of Carcinoma of one breast with Sarcoma of the other existing at the same time and removed from a woman aged 50 years.—Dr. F. H. Barendt showed a specimen of Comedo.—Dr. R. J. M. Buchanan showed specimens of Epithelioma'a from horses—(1) eyelid, (2) penis, (3) tail, the last being markedly pigmented.—Dr. J. E. Gemmell showed a surface Papilloma of an Ovary and a specimen of a Fibroma of an Ovary.—The specimens were discussed by the Chairman, Sir W. M. Banks, Mr. F. T. Paul, Mr. G. P. Newbolt, Mr. Thomas, Dr. Alexander, Dr. Raw, Dr. Gemmell, Dr. J. Barr, and Professor H. Briggs.—Mr. Paul gave a demonstration on Mastitis in its Relation to Tumour Formation. Mr. Paul evidenced the relation between chronic mastitis and varied tumour formations and illustrated his communication with numerous microscopical sections and a unique series of photomicrographs.—A discussion followed, in which the Chairman, Sir W. M. Banks, Mr. Rushton Parker, and Professor Briggs took part, and Mr. Paul replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 6th at the Dispensary, Broad-street, Mr. G. B. Wray, the President, being in the chair.—It was resolved, on the proposition of the President, seconded by Dr. H. Handford, that the members record on the minutes of the society their deep sense of grief at the loss they, in common with the empire, had suffered through the death of their dearly loved Queen Victoria and that their sincere sympathy go forth to His Imperial Highness and all the Royal Family in their time of bereavement.—Dr. Ransom then communicated his paper on the Suppression of Phthisis, dwelling on the responsibility of medical men. He maintained that the education of the individual and the public by them was essential to the successful treatment of phthisis. He instanced the great value of residence for a time in a sanatorium for educational purposes, *re* the disposal of sputum and its disinfection, the regulation of exercise and diet, the use of the thermometer, the taking of weight, the value of fresh air, and the harmlessness of cold; and that the period of convalescence be spent in some light outdoor employment and back to a country life. Agricultural training colleges would be of great value as supplements to sanatoria and endeavours should be made to start coöperative farms and horticultural colonies. Dr. Ransom advocated the voluntary notification of phthisis, that milk and flesh of cattle should be inspected by skilled officers, and that compulsory notification of ulceration in cows' udders should be insisted on.—The President, Dr. Handford, and Dr. P. Boobbyer also spoke on the subject.—Dr. Ransom showed pathological specimens from a young girl, aged 20 years. They were a soft growth in the body of the fourth dorsal vertebra and both ovaries of the size of oranges covered with nodular growths of the size of small beans (the growth was a round-celled sarcoma).

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—The fifth meeting of the session was held on Feb. 11th, Mr. H. E. Clark, the President, being in the chair.—Dr. Charles Workman showed: (1) A Brain the seat of extensive Tuberculous Disease and Hydrocephalus; (2) three Brains with Tumour Formation, with Microscopical Section of the same; (3) a Heart with Double Mitral Orifice and Valves; (4) a Heart showing Enormous Dilatation and Hypertrophy; (5) an Aneurysm of the Arch of the Aorta with Hypertrophy of the Left Ventricle; and (6) a Heart showing Hypertrophy of the Left Ventricle with Aneurysm of the Wall due to Fibrous Transformation.—Dr. Walter K. Hunter showed Microscopical Preparations of the Blood from a case of Splenic Leukæmia.—Dr. T. K. Monro showed: (1) A boy, aged 12 years, presenting Atrophy of the Right Testicle following Rheumatic Orchitis; and (2) a woman, aged 26 years, with Loss of Stereognostic Sense in the Right Hand (senses of touch, pain, and temperature preserved).—Dr. H. Rutherford showed: (1) A Rectal Dermoid removed by the Para-sacral Route; (2) Double Coxa Vara in a Child, aged seven years; (3) Congenital Dislocation of the Hip (to contrast with the preceding case); (4) Microscopical Sections of a Wood's Painful Subcutaneous Tumour; and (5) a Skiagram of a case of Vertical Dislocation of the Patella without rupture of the quadriceps or ligament treated by open operation.—Dr. David Knox showed: (1) A girl, aged 18 years, with Hypertrophy of the Right Mamma; and (2) a specimen of Round-celled Sarcoma involving both Hemispheres of the Brain.—Dr. Hugh Maclaren showed: (1) A specimen exhibiting an Abnormal Situation of the Vermiform Appendix; and (2) specimen of Embolism of the Femoral Artery, Thrombosis of the Femoral Veins, and Embolism of the Pulmonary Artery which had caused death.

IPSWICH CLINICAL SOCIETY.—A meeting of this society was held on Feb. 14th, Mr. James Hossack being in the chair.—Dr. H. H. Brown read a very interesting paper upon Gastric Ulcer and its Complications. He also spoke with reference to several cases which he had met with in private practice, showing at the same time a specimen of a stomach with a perforating ulcer of that viscus and duodenum also.—A discussion then followed, Mr. J. F. C. Hossack, Dr. W. W. Sinclair, Mr. Staddon, Mr. C. G. Mosely, Mr. A. Y. Pringle, Dr. W. A. Gibb, and Dr. Ward joining in, and Dr. Brown replied.—Dr. Ward showed two specimens. The first was a Brain from a chlorotic girl showing cerebral thrombosis. The patient, a young girl, suddenly became aphasic and drowsy, and rapidly becoming comatose died very shortly without regaining consciousness. She had

been suffering from anæmia. There was no history of syphilis or tubercle. The second specimen was a portion of the Femoral Artery of a boy with a rent three-eighths of an inch long in it. The history was as follows. The boy was admitted into hospital suffering from a false aneurysm of the thigh; a month previously he had been shot in the thigh with a pocket pistol which he had been carrying in his pocket. The bullet was still *in situ*, and was found with the x rays. On cutting down this condition of the femoral artery was discovered. He had been sent in on account of recurrent hæmorrhage.

CARDIFF MEDICAL SOCIETY.—A conjoint meeting of this society and the Biological Section of the Cardiff Naturalists' Society was held at University College, Cardiff, on Feb. 8th, Dr. E. Walford and Mr. T. H. Thomas, the respective Presidents, presiding.—Dr. D. R. Paterson read a paper and illustrated it with lantern slides on the Life-history of the Malarial Parasite. The experimental methods which led to the identification of the parasite were described and illustrated and its life-history and the various methods of its reproduction were fully gone into. Finally, the manner of recognition of the particular variety of mosquito which harboured the parasite was indicated.—Professor W. Newton Parker read a paper on Parental Care in the Lower Vertebrata. He gave an account of a number of instances amongst fish and amphibians in which sundry methods had been adopted for the protection of the eggs and the young. Various forms of nests were described, including those of several species of hyla and of rhacophorus schlegeli, and also numerous contrivances for the protection, nutrition, and respiration of the larvæ both within and without the body of the parent. The paper was illustrated by lantern slides.—Numerous specimens of biological and physiological interest were exhibited in the physiological laboratory at the conclusion of the papers by Professor A. F. Dixon, Dr. Swale Vincent, and others.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 22nd, Mr. W. C. Worley, the President, being in the chair.—Mr. F. Hewitt Oliver showed (1) a very advanced Development of Molluscum Fibrosum in a man, aged 45 years, whose growths had existed from infancy. The distribution was general but most thickly on the abdomen. 2. An Infant with Genu Retrorsum whose Patellæ were Impalpable. Passive flexion a month ago was much limited and hyperextension of the leg existed. Now, without treatment, complete passive flexion was easy and hyper-extension of the leg was checked.—Dr. J. S. Risien Russell read a paper on the Modern Treatment of Idiopathic Epilepsy, emphasising the importance of an accurate diagnosis. To this end he advised the routine use of an analysis of the urine and an examination of the fundus oculi. He reviewed a large number of drugs that were advocated by various writers and, giving some praise to digitalis, belladonna, and borax, he thought bromide of potassium the most useful of all, especially when given with discrimination as to dose and time of the administration of the dose. Yet the patient, as a whole, must be given consideration and all defects remediable cured.

SOUTHPORT MEDICAL SOCIETY.—A meeting of this society was held on Feb. 13th, Dr. R. Harris being in the chair.—Dr. W. Permewan (Liverpool) showed a patient from whom he had recently removed a Papilloma of the Left Vocal Cord and made some observations on the best method of removal of these growths.—A case of Temporary Facial Paralysis following mastoid operation was also shown, which was followed by a discussion.—Mr. Reinhardt Anderson showed a boy on whom he had operated for Hydatid Cyst of the Liver and also a specimen of Cancer of the Mediastinum Infiltrating the Lung.

INCORPORATED SOCIETY OF TRAINED MASSEUSES.—The annual meeting of this society was held on Feb. 15th. The reports from the sub-committees showed a steady progress in the work of the society since its incorporation last July. The council aim at a high standard of efficiency for members of the profession and they only grant their certificate to those who have satisfied the examiners in their practical and theoretical work. Certificate-holders are not members unless nominated and elected by the council, and to the members further opportunities are offered of continuing their studies by special lectures in anatomy and other subjects. The honorary secretary is Miss L. Grant, 12, Buckingham-street, Strand.

Reviews and Notices of Books.

The Essentials of Regional Anatomy. By RICHARD J. A. BERRY, M.D., F.R.C.S. Edin., F.R.S.E., Lecturer on Anatomy in the New School of Medicine of the Royal Colleges, Edinburgh; Examiner in Anatomy to the University of St. Andrews, and to the Royal College of Surgeons, Edinburgh. Edinburgh and London: William Green and Sons. 1900. 8vo. Pp. 484.

THE author's intention in preparing this volume has been to provide for the medical student a work on human anatomy in which there shall be no facts with which he need not concern himself. Dr. Berry considers that at the present day the student of medicine is overworked and that his curriculum is made unnecessarily severe in some respects, especially in the study of physiology, and under these circumstances the author thinks that there is a risk of anatomy not receiving the attention it deserves as the real basis of medicine and surgery. We go far with Dr. Berry in the opinion that medical students frequently have to devote much time to studies which are of but little ultimate value, and we therefore sympathise with this attempt to assist the student, to whom the present work will be of value in presenting an accurate but somewhat brief account of the anatomy of the human body. There are no illustrations, but the book is interleaved with blank paper, on which the author hopes that the student will draw sketches of his dissections or will reproduce the diagrams drawn for him on the blackboard. We are afraid that in this Dr. Berry will be disappointed.

Although there may be differences of opinion as to the need for this work, there must be unanimity as to the excellent way in which the book has been prepared. We think, however, that the author would do well to add some diagrams. If judiciously chosen they would serve to increase distinctly the value of the book.

Syphilis of Children in Every-day Practice. By GEORGE CARPENTER, M.D. Lond. London: Baillière, Tindall, and Cox. 1901. Medical Monograph Series. Illustrated. Pp. 110. Price 3*s.* 6*d.*

THIS monograph on the subject of syphilis in children is only concerned with the congenital variety. With regard to the severity of the symptoms and the frequency of its incidence the author considers that the improvement which is manifest in these respects within recent times is due partly to attenuation of the virus and partly to the relative immunity of the subject. The manifestations of the disease are grouped systematically according to the various organs and tissues affected, commencing with the lesions of the skin, mucous membrane, and teeth, and proceeding to those of the lungs, liver, spleen, and bones. The important association of rickets and syphilis is fully discussed and the part which each plays in the production of Parrot's nodes is reviewed from the pathological standpoint. The author evidently inclines to the belief that a syphilitic process is mainly if not exclusively responsible for this aberrant development of bone. According to the author Parrot's nodes are present only to the extent of one per 1000 in cases of rickets apparently uncomplicated by syphilis. The question naturally arises, What is the distinction between the familiar bossing of the frontal and parietal bones in rachitic children and true Parrot's nodes? The conclusion is obvious, that either syphilis is extraordinarily rife among all classes or that Parrot's nodes are separate and distinct, both etiologically and pathologically, from ordinary slight degrees of bossing. With regard to treatment Dr. Carpenter insists on the

exhibition of mercury for at least one year and attaches but little importance to the influence of this drug on the subsequent development of the teeth. He regards mercury as an energetic producer of red blood corpuscles. Apart from mercury and the iodides treatment is summarily dismissed. The maintenance of nutrition in syphilitic infants, a matter of such practical difficulty, is summed up in the following sentence: "If the mother cannot nurse, and a wet nurse is out of the question, a suitable milk diet must be substituted." There is no new or original feature in any section of this little volume. On the other hand, nothing, except certain matters of treatment, of clinical importance is omitted. The illustrations are excellent and are freely distributed throughout the text.

Difficult Labour: A Guide to its Management for Students and Practitioners. By G. ERNEST HERMAN, M.B., F.R.C.P. Lond. New and revised edition. With 165 Illustrations. London: Cassell and Co. 1901. Crown 8vo. Pp. 470. Price 12*s.* 6*d.*

SINCE the publication of the first edition in 1894 Dr. Herman's book has been issued three times as a reprint and once in a revised form. The appearance of this new and revised edition is to be welcomed. It bears ample proof of careful revision without any marked increase in its size. Three new illustrations have been added, including one of spondylizema and two of central rupture of the perineum. Amongst the sections that have been modified or added to we notice those upon General Enlargement of the Child, Morbid Enlargements of the Fœtal Body, Mechanism of Labour with the After-coming Head, Can Post-partum Hæmorrhage be Prevented? and the Mechanism of Labour in Kyphotic Pelves. The most important alterations are in the chapters upon Symphysiotomy and Cæsarean Section. Writing in 1894 Dr. Herman hesitated to recommend symphysiotomy. Now he is apparently convinced that there is sufficient evidence to show that no detrimental after-effects follow the operation, and he advises its employment in certain suitable cases. He recommends the subcutaneous method and describes the operation as he performs it. In this description we think the author hardly enters sufficiently into detail. He says, for instance, "Press the point of the knife through the mucous membrane opposite the middle of the symphysis pubis." As there is no mucous membrane anterior to the frenulum clitoridis, he means, no doubt, the skin. A student without any previous knowledge reading this might well be misled. In the chapter on Cæsarean Section it is recommended when it is desired to render the patient sterile that the body of the uterus should be removed, on the grounds that the patient will be free from child-bearing and from menstruation, and because recovery after this operation is as easy as when the uterine wound has been sewn up. This is a matter upon which a considerable difference of opinion would no doubt exist amongst obstetricians.

This work has already met with considerable success and we can confidently recommend the new edition.

Normal Histology. By EDWARD K. DUNHAM, Ph.B., M.D., Professor of General Pathology, Bacteriology, and Hygiene in the University and Bellevue Hospital Medical College, New York. Second edition. London: Rebman, Limited. 1900. Pp. 318. 244 Engravings. Price 12*s.* net.

THIS work is intended primarily for the medical student, and is planned with due consideration to the facts that histology must be taught under conditions which require economy of time, and that it must have a place at the beginning of the medical curriculum when the students' technical facility is least developed. It is therefore concise in its descriptions and the histological methods given are selected for their simplicity and usefulness. Throughout the work stress is laid on the relations existing between structure and function and consequently at times the author trenches on the ground of physiology; for this most teachers of medical students will consider that no justification is needed. The book is not intended as a laboratory handbook, but it is recognised that histology must be taught in the laboratory and that a course of demonstrations and practical work are required to complete what is taught in the text.

After a short introduction there is a clear description of the cell and of the phenomena of karyokinesis, followed by chapters on the elementary tissues. In each case the general characters of the tissues are given categorically and then variations in these characters with the resulting variation in the character of the tissues are discussed. The different appearances in sections due to changes in the plane of section are carefully pointed out. Tissues of special function and the histology of the various organs are then treated. There is a very concise but clear description of the histological elements of blood and lymph. The reproductive organs and the central nervous system with the organs of special sense are described at some length. Throughout attention is paid to those points likely to be of importance to the medical student. The illustrations, which are derived from various sources, are numerous and well reproduced; those illustrating the nervous system are chiefly from Cajal. Part II., on Histological Technique, occupies 40 pages, and bearing in mind the object of the book the processes are well selected and very well described. The author has not always the courage of his convictions, as a page is occupied by Golgi's method, though it is admitted to be too difficult and the details necessary for carrying it out are omitted.

The book should serve the purpose for which it was written, but it will not replace the manuals at present used by English students.

Manual of Personal Hygiene. Edited by WALTER L. PYLE, A.M., M.D. Illustrated. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 338. Price 6*s.*

THERE are already indications that the advances in sanitary science and public health which have marked the second half of the past century are to be succeeded by an era of reform in matters which relate to personal hygiene. The manual under review is one of the outward and visible signs of this movement, it is the united production of a "combine" of American specialists in the various branches of this comparatively new science. Dr. C. G. Stockton contributes the section on Digestion and shows how violation of the rudimentary laws of physiology as applicable to food and dietetics may be responsible for general ill-health; the care of the teeth constitutes an important factor in the maintenance of a normal standard of nutrition. Dr. G. H. Fox in the next chapter treats of the Hygiene of the Skin and is followed by Dr. Ingals on the Voice and Respiration. This chapter includes the important subjects of adenoids, deformities of the chest, and spinal curvatures, the causes which lead to these conditions, and the mode of prevention. The Hygiene of the Ear, another important factor in the intellectual development of children, is adequately dealt with by Dr. B. A. Randall, while Dr. Pyle himself devotes a long chapter to the subject of the Eye, its Uses and Abuses, emphasising the dangers of certain kindergarten methods which entail constant examination of small objects at near focus. The general aspects of school hygiene are included in this chapter and deserve close attention from practitioners in this country, where "child-culture" is still regarded rather as a fad than as a serious branch of preventive medicine. The Hygiene of the Brain and Nervous System is undertaken by Dr. J. W. Courtney and the section covers ground of equal

importance since it embraces the subjects of nerve strain and nerve rest. The final chapter is written by Dr. G. N. Stewart and is devoted to the subject of Physical Exercise.

Perhaps in no country in the world has the neglect of the laws of personal hygiene produced more disastrous consequences than in the United States, where keen competition and the unhealthy conditions of urban segregation have reached a dangerous degree of development. Neurasthenia and other forms of nerve degeneration, due to what Dr. Courtney inelegantly calls "*worriment*," are familiar conditions in the United States, and hence specialists in these and allied subjects have a wide field for their investigations. We in this country should be grateful for the comprehensive manner in which experience thus gained has been systematised in Pyle's Manual of Personal Hygiene.

Éléments d'Anatomie Gynécologique. By PAUL PETIT. With a Preface by Professor PIERRE SEBILEAU. With 32 original Plates. Paris: Carré et Naud. 1901. 8vo, pp. 222. Price 16 francs.

THIS book is the outcome of work done by M. Paul Petit in the laboratory of Professor Pierre Sebileau. The anatomy of the pelvis and the organs it contains is often but imperfectly dealt with even in the best text-books, and the anatomical details required by an operating gynæcologist can only be adequately supplied by one who is himself accustomed to see and to practise such operations. The present book is intended to give not only a complete account of the pelvic viscera, but more particularly a description of the other important structures in the pelvis—namely, the muscles, fasciæ, vascular sheaths, cellular tissue, and the important lines of cleavage of the fibrous tissues. The work is divided into four parts. The first deals with the superficial and deep anatomy of the external genitalia and the perineum; the second with the pelvic region proper, including the pelvic viscera; the third with the antero-lateral portion of the abdominal wall; and the fourth with the iliac fossa. M. Petit's previous publications show that he has studied these regions with much care and detail, and the results which he records in the present work are of corresponding value. A great deal of space is devoted to descriptions of the fasciæ of the pelvis, both superficial and deep, and more especially to the relation of the fasciæ and cellular tissues of the viscera. The vascular pedicles of the uterus, vagina, bladder, and rectum are given in detail, and their importance in relation to the various operations practised for removal of the uterus is pointed out. Amongst other important sections we may call attention to those dealing with the sac of the dartos, the gland of Bartholin, the perineum, the cavum Retzii, the round ligament, and the anatomy of Alexander's operation and the operation of cystopexy. The section of the book of most value is perhaps that devoted to a description of the "vessel sheath" of Farabeuf, and its relations to pelvic cellulitis and other inflammatory conditions occurring in the pelvis. The author points out how inadequate the term "parametritis" is to describe the various forms of inflammation of the pelvic cellular tissue, and holds that the word "cellulitis" should be used qualified by the name of the particular region affected. In this he is in accord with most modern writers upon gynæcology, amongst whom the terms "parametritis" and "perimetritis," are rightly falling into disuse. A large number of full-page plates illustrative of the various dissections made are given. They are on the whole clear and well reproduced. We wish, however, that the author had stated rather more fully the position of the pelvis in the various descriptions. Owing to the want in many cases of a clear indication as to what direction any particular dissection is regarded from, the details are often hard to grasp.

The work, as a whole, is a valuable contribution to the anatomy of the pelvic region and does credit to its author.

LIBRARY TABLE.

Dental Anatomy Note Book. For use in conjunction with Tomes's "Dental Anatomy," the South Kensington Museum, and personal instruction. By DOUGLAS GABELL, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S. R.C.S. Eng., Assistant Surgeon at the Dental Hospital of London. Second edition. London: Claudius Ash and Sons, Limited. 1900. Price 3*s.* 6*d.* net.—That this little book should have so quickly reached a second edition is sufficient proof of its value to the dental student. Aid books to different subjects are, as a rule, to be condemned, the student utilising them simply for the purposes of cramming. Mr. Gabell's note-book does not come under this category, and of its kind it is unique. It does not aim at taking the place of larger books on the subject, but directs the student's attention to what he should learn and also gives him some idea of how to learn it. The subject is clearly and neatly arranged, ample room being left for the student to make his own supplementary notes. A point that strikes us in reading the notebook is that in places it is too scanty in its information and help.

Life in an Open-air Sanatorium. By CHARLES REINHARDT, L.S.A., M.D. Brux. Illustrated. London: John Bale, Sons, and Danielsson, Limited. 1900. Pp. 104. Price 1*s.*—This little brochure on the open-air treatment is evidently intended for the instruction of the public. The medical profession may, however, find the information which it affords regarding our home sanatoria of practical use if in doubt as to the choice of a suitable institution for a phthisical patient. Dr. Reinhardt is strongly in favour of British as opposed to foreign sanatoria, since the latter have recently shown a tendency to degenerate into mere commercial speculations on the lines of hotels rather than to order themselves as places for the treatment of the sick. He strongly urges the necessity for early treatment, and where circumstances allow suggests a stay of at least four or five months in the establishment.

The Story of Thought and Feeling. By FREDERICK RYLAND, M.A. The Library of Useful Stories. London: George Newnes, Limited. 1900. Pp. 212. Price 1*s.*—The study of psychology may be regarded as a luxury rather than as an essential element in an ordinary medical education; like the study of other branches of speculative philosophy it may involve the every-day problems of medical practice in profitless and unnecessary consideration. "The Story of Thought and Feeling" will serve as an excellent introduction to the study of mental processes for those who wish to pursue the subject, and it is written, so far as the scientific nature of the question allows, in simple and untechnical language. Any reader who can devote a few hours to the perusal of 200 small pages will find himself equipped with a very fair understanding of the meaning of consciousness, perception, thought, and language, as well as of those other mental processes which are included in the science of psychology.

The Temples and Ritual of Asklepios. By RICHARD CATON, M.D. Edin., F.R.C.P. Lond. With 34 Illustrations. Second Edition. London: C. J. Clay and Sons. 1900. Pp. 46. Price 3*s.*—Although we are more familiar with Dr. Caton as an original investigator in the fields of physiological research many of us will read with interest the first-fruits of his labours as an archæologist. From a careful study of the remains of the temples of Asklepios, and notably those at Epidaurus and Athens, Dr. Caton has been enabled to make certain suggestive speculations as to the uses and objects of some of the buildings which are more or less constant features of such temples of health. For instance, the suggestion that the Thalos was the place where the sacred serpents were housed, fed, and venerated seems to be supported by a certain amount of

collateral and direct evidence, and that certain other extensive quadrangles were of the nature of hostels for the accommodation of patients appears a natural and common-sense assumption. The ritual and mysticism attendant on the worship of Asklepios will probably ever remain in obscurity, but Dr. Caton has at least made an attempt to present us with an intelligible picture of the healing art as practised some four or five hundred years before the birth of Christ at the Greek temples of health. The contents of this little book were originally presented to the public in the form of lectures at the Royal Institution, on which occasions Dr. Caton's researches were more profusely illustrated than has been found possible in the present book form. Nevertheless, the photographs and drawings which it has been possible to reproduce are full of interest and sufficiently illustrative of the points which the author chiefly emphasises in the text.

La Rage. Par le Dr. AUGUSTE MARIE, avec une Préface de M. le Dr. E. ROUX. Paris: Masson et Cie. (*Rabies.* By Dr. AUGUSTE MARIE, with a Preface by Dr. E. ROUX.) Pp. 180. Price 2 francs 50 centimes.—This little volume forms one of the series entitled "Encyclopédie Scientifique des Aide-Mémoire," and is written by two experts in the subject, for Dr. Marie is director of the Anti-rabic Institute of Constantinople and Dr. Roux is the sub-director of the Pasteur Institute. The preface of Dr. Roux deals with the subject of rabies before and after the time of Pasteur and concludes by giving a description of Pasteur's well known method of prophylaxis. Possibly, says Dr. Roux, we shall one day be able to cure rabies; at present we can only prevent it. Dr. Marie gives a short historical summary of the knowledge of the disease, and in his first chapter deals with the malady as exhibited under different forms in different animals. A chapter follows on the pathological anatomy of rabies, and next is given a description of the virus, together with an account of Pasteur's researches in diminishing or exalting the powers of the poison. A chapter on epidemiology follows and then comes the all-important subject of prophylaxis from a sanitary point of view. Muzzling orders together with the destruction of ownerless or wandering dogs are the most hopeful measures, and where these are strictly enforced rabies practically disappears. The next chapter is taken up by a description of Pasteur's method of immunisation and of variations on this method practised by other observers. The book concludes with statistics from the various anti-rabic institutes, the figures of which go to show the prime importance of commencing treatment as soon as possible after the bite. Treatment of the disease when once declared can only be palliative. This little book is a useful summary of our knowledge, so far as it goes at present, of this terrible complaint.

First Aid to the Injured and Sick. By F. J. WARWICK, M.B. Cantab., M.R.C.S. Eng., and A. C. TUNSTALL, M.D., F.R.C.S. Edin. Bristol: John Wright and Co. London: Simpkin. 1901. Pp. 242. Price 2*s.* 6*d.*—This is one of the very many books published on first aid. The authors are both Volunteer Medical Staff officers and know their subject. The book is simply written, though we should say that there was rather too much anatomy and physiology in the first part for unprofessional readers. But the practical part is good. In the section upon Shock by Electricity we think that there are one or two points which should be made clearer. Thus we find, "The danger of a current is in proportion to its intensity." This is not strictly true, for the quantity of current also has to be taken into consideration. A small Leyden jar will give a current of very high intensity, but its output is so small that the effects are not dangerous. Again, we find directions given for releasing a sufferer from a "live" wire, which are good as far as they go, but no mention is made of the advisability of the rescuer "unearthing" himself by standing on an india-rubber mat or a pile of dry woollen rugs or something similar. In many cases the most easily procured india-rubber articles are tobacco pouches.

(1) *Science in the Daily Meal.* Pp. 45. Price 6*d.* (2) *Fruits, Nuts, and Vegetables.* Pp. 102. Price 6*d.* By ALBERT BROADBENT, F.R.H.S. Manchester: Albert Broadbent. 1900.—These two little books are apparently written by a vegetarian and we think we detect a flavour of homœopathy as well. But the foible and the heresy apart, they contain some excellent recipes for simple dishes and valuable hints as to cookery. Vegetables are far too little used in this country as food stuffs served apart from meats, and salads of cooked vegetables allowed to get cold are almost unknown. Yet, especially in the summer, a vegetable, fish, and fruit dinner is always acceptable. On page 32 of No. 2 we find the following remarkable statement concerning barley: "Its value is well known as a drink in the form of barley water, or 'barley bree,' as it is called in Scotland." We never before understood the inner meaning of the old Scots song, "Willie brewed a peck o' maut." The three blithe companions, it will be remembered, sang,

> "We are na fou, we're no that fou,
> But just a drappie in our e'e;
> The cock may craw, the daylight daw,
> But we will taste the barley bree."

There is no reason why the drinking of barley water should make anyone "fou," but somehow barley water goes oddly with the assertion—

> "Who last beside his chair shall fa'
> Shall be the king amang us three."

JOURNALS AND MAGAZINES.

The Journal of Anatomy and Physiology, Normal and Pathological. Conducted by Sir WILLIAM TURNER, F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. M'KENDRICK, F.R.S. Vol. xxxv., Part 2. January, 1901. London: Charles Griffin and Co. Price 6*s.*—The articles contained in this number are: 1. By Dr. Peter Thompson: On the Arrangement of the Fasciæ of the Pelvis and their Relationship to the Levator Ani. With five plates. 2. By Dr. William Brodie Brodie: On the Destruction of Leucocytes, in which the author describes phagocytes which are produced in lymphatic glands and have for their function the destruction of leucocytes. A plate is appended to the article showing the appearances observed. 3. By Dr. Charles Powell White: A Differential Stain for Muscular and Fibrous Tissues. A useful means of distinguishing between these tissues. 4. By Professor W. H. Thompson of Belfast: Degenerations Resulting from Lesions of the Cortex of the Temporal Lobe. Monkeys and marmosets were exclusively employed in Professor Thompson's experiments. The degenerations, which are numerous, are carefully described and are illustrated by a plate and by drawings in the text. 5. By Professor Christopher Addison: On the Topographical Anatomy of the Abdominal Viscera in Man, especially the Gastro-intestinal Canal. This is the third part of a long memoir and is illustrated by five plates. Careful measurements are given of the different organs. 6. By Dr. Otto Thilo of Riga: Stop or Click Mechanism in the Animal Kingdom, with two plates. The author adduces various examples in which muscular effort is saved by mechanical contrivances, citing especially and giving drawings of such mechanism in the dorsal fin of the stickleback and other fish. A very ingeniously written paper. He shows that the principle is adopted in the construction of the Yale lock. 7. By Dr. J. O. Wakelin Barratt of the West Riding Asylum, Wakefield: Observations on the Structure of the Third, Fourth, and Sixth

Cranial Nerves. This article, though short, is a valuable one and represents an amazing amount of careful work. The above-named nerves were dissected out along their whole course and after being hardened were sectioned along their entire length. 8. By Dr. Walter H. Gaskell, F.R.S.: On the Origin of Vertebrates deduced from the Study of Ammocœtes. This article constitutes the ninth part of a long argument on a theory advanced by Dr. Gaskell in regard to the phylogeny of the Vertebrata contained in previous numbers of the Journal and is occupied with a discussion on the probable mode of origin of the vertebrate eye. 9. The last article contains the proceedings of the Anatomical Society of Great Britain and Ireland.

New Inventions.

A SYRINGE FOR THE NOSE AND EAR.

THE accompanying illustration shows a syringe for cleansing the nose and ear, the scale on which it is drawn being two-thirds of the natural size. The instrument is simple in construction and cannot well get out of order. The glass nozzles are replaceable and can be easily kept clean and

sterilised. The indiarubber bag may be washed out with strong antiseptic solution when necessary and a few minutes' boiling does not seem to damage it. The cost is such as to bring it within the reach of hospital patients. The syringe is made by Messrs. Allen and Hanburys from my suggestion.

W. H. KELSON, F.R.C.S. Eng.

NEW OVARIOTOMY TROCAR TUBE.

WHEN tapping an ovarian cyst the difficulty of getting the fluid to travel down the exit tube attached to the trocar has been experienced by many operators. The one depicted in the illustration below has been designed to meet this

difficulty. When the cyst has been tapped and the contents will not flow a jug of water poured into the funnel-shaped opening at the side of the rubber tube will create a vacuum and the fluid from the cyst should at once begin to run; if it does not the rubber air-ball should be compressed, when the contents of the cyst, if fluid or gelatinous, should certainly find exit. The makers are Messrs. Arnold and Sons of Smithfield, London, E.C.

Cheltenham. ALEXANDER DUKE.

AN INTERESTING LIST.

THE following is a list of the Fellows of the Royal College of Physicians of London and a few (old) Licentiates or Members who held appointments to Her late Majesty Queen Victoria as physicians:—

1837.—Sir Henry Halford, Bart., physician to the Queen; Sir James M'Grigor, Bart., Sir Henry Holland, Bart., and Dr. Richard Bright, physicians extraordinary; Sir James Clark, physician to the Queen and to the Queen's household (*Licentiate*); and Dr. Neil Arnott, physician extraordinary (*Licentiate*).
1838.—Dr. Peter Mere Latham, physician extraordinary; and Dr. William Frederic Chambers, physician to the Queen and to the Queen Dowager.
1842.—Dr. John Forbes, physician to the Queen's household (*Licentiate*).
1846.—Sir Charles Locock, Bart., physician accoucheur.
1847.—Dr. Robert Ferguson, physician accoucheur.
1859.—Sir Thomas Watson, Bart., physician-in-ordinary; and Dr. William Baly, physician extraordinary.
1861.—Dr. Francis Hawkins, physician to the Queen's household; and Sir William Jenner, Bart., physician-in-ordinary.
1866.—Sir Thomas Galbraith Logan, honorary physician.
1868.—Sir Alexander Armstrong, honorary surgeon.
1870.—Dr. Alexander Nisbet (*Member*) and Dr. Benjamin Proctor Rooke (*Member*), honorary physicians.
1871.—Sir George Burrows, physician-in-ordinary; and Dr. Wilson Fox, physician extraordinary.
1873.—Sir William Gull, Bart., physician extraordinary.
1874.—Sir Edward Sieveking, physician-in-ordinary; and Sir Joseph Fayrer, Bart., honorary physician.
1875.—Dr. Charles J. B. Williams, physician extraordinary.
1876.—Sir James Alderson and Dr. Arthur Farre, physicians extraordinary.
1879.—Sir J. Russell Reynolds, physician to the Queen's household.
1881.—Sir William Richard Edwin Smart, honorary physician (*Member*).
1883.—Dr. George Owen Rees, physician extraordinary.
1889.—Dr. Thomas Graham Balfour, honorary physician.
1890.—Sir George Johnson, physician extraordinary; and Sir R. Douglas-Powell, Bart., and Sir James Reid, Bart., physicians-in-ordinary.
1891.—Sir Richard Quain, Bart., and Sir Alfred Garrod, physicians extraordinary.
1892.—Dr. Thomas Edmonston Charles, honorary physician.
1897.—Sir Samuel Wilks, Bart., physician extraordinary.
1898.—Sir Thomas Barlow, Bart., physician to the Queen's household.
1899.—Dr. James Edward Pollock and Sir William H. Broadbent, physicians extraordinary.
1900.—Dr. Alexander Bradshaw (*Member*), honorary physician, and Sir Thomas Barlow, Bart., physician extraordinary and physician to the Queen's household.

BRISTOL HEALTH COMMITTEE.—At a meeting of the Bristol Health Committee held on Feb. 19th it was reported that the expenditure for the health department, infectious hospitals, and port sanitary authority for the past six months amounted to £11,469. This exceeded by nearly £2000 the estimated expenditure.

BATH SOUTHERN DISPENSARY.—The annual meeting of the subscribers of this institution was held on Feb. 12th under the presidency of the mayor. The medical report stated that 649 patients had been attended during the year, and of these 267 were visited at their own homes. The financial statement showed a satisfactory balance.

THE LANCET.

LONDON: SATURDAY, MARCH 2, 1901.

Crime and Punishment.

IN the February number of the *Nineteenth Century* Dr. ROBERT ANDERSON, the Assistant Commissioner of Police of the Metropolis, discusses the national penal system under the uncomplimentary title, "Our Absurd System of Punishing Crime." Anything written on the subject of crime or criminals by a public official of such ripe experience cannot fail to be of interest to the community. Upon certain statistics of metropolitan crime—statistics which we are bound at the outset to say we do not accept as being in themselves conclusive—Dr. ANDERSON satisfies himself that it is a fact, and a fact of which every expert is aware, "that while crime generally is diminishing *professional* crime is on the increase." He goes on to say that this development of the professional criminal is becoming a serious public danger. Dr. ANDERSON addresses himself to the task of averting this danger, and his thesis is that "while crime in general is an ineffaceable blot upon our civilisation, professional crime is preventable and might be suppressed." He divides professional criminals, essentially burglars, housebreakers, and shopbreakers, into two classes: those who are so utterly weak or so hopelessly wicked that they cannot abstain from crime, and those who pursue a career of crime deliberately, with full appreciation of its risks. We cannot say that we regard this classification as being either definite or practical, for it is difficult to know what value to put upon the terms "weak" and "wicked" in this relation, while, we take it, few burglars proceed to work without a full appreciation of the risk they are running. However, let us try to follow Dr. ANDERSON in his way of working out a problem that is by no means easy.

Our methods of dealing with the weak and wicked are, he says, unintelligent and harsh. Our methods in the case of professional criminals, those who are criminals by deliberate choice, he looks upon as being indefensible and equally unintelligent. It is more especially to this class of professional criminals that Dr. ANDERSON is anxious to direct attention. After dealing with some of the moral aspects of crime, and after brushing aside the part played by humanity-mongers in the matter, he recites some individual instances of ineffectual sentences passed on habitual or professional criminals. He then gives it as his opinion that the serious increase of professional crime is due mainly to the fact that, owing to the decrease in ordinary crime, sentences are now so lenient that they have ceased to be a terror to the professional criminal. He goes on to say that "if an Act were passed fixing 12 months' imprisonment as a minimum sentence and consigning the worst sort of professional criminals to the gallows it would, I believe, though ill-advised, be better, and (I have no hesitation in adding) more humane than our present methods." In the end, Dr. ANDERSON advocates imprisonment for life in the case of habitual and professional criminals, and he bases his penal scheme upon the criminal's love of liberty. He says that "in setting themselves to punish crime our criminal courts are pursuing a wrong system, a system unworthy of the age, a system begotten of mediæval superstition and ignorance." Dr. ANDERSON is no doubt right when he insists upon a full and open inquiry into the prisoner's character and antecedents, an inquiry upon a more elaborate, formal, and dignified footing than the investigation which is now carried out by some judges. The result of this inquiry would determine whether the prisoner is "a citizen or an outlaw." Then, if he is an outlaw and if he belongs to the first, the weak or wicked, class, Dr. ANDERSON would have him "sent to an asylum prison where his life can be spent in useful labour with every reasonable alleviation of his lot." If, on the other hand, he belongs to the deliberate professional criminal type "let him be deprived of the liberty he abuses." Bearing in mind that only crimes against property are under consideration it is not unnatural that Dr. ANDERSON at this point introduces into his scheme the subject of the abolition of the market for stolen property. "Let the prisoner," he says, "be required to disclose what he has done with his booty, and if he refuses, or fails to satisfy the court that it is out of his power to do so, let there be but one sentence—imprisonment for life." We are by no means so sanguine as Dr. ANDERSON is that his suggestion, of which he thinks nine-tenths of the community will unreservedly approve, would, if carried into effect, succeed in preventing or suppressing professional crime. We do not think a judge and jury would be induced to consign a man to life imprisonment upon an issue that was not before the court, nor can we imagine a legislature having the temerity to authorise or to ask them to do so. Dr. ANDERSON, in urging imprisonment for life on an extended scale, takes shelter behind the eminent jurist Sir JAMES FITZJAMES STEPHEN, whose advocacy of an extension of the death penalty is given in the following quotations: "I would punish with death offences against property only upon great deliberation and when it was made to appear, by a formal public inquiry held after a conviction for an isolated offence, that the criminal really was an habitual, hardened, practically irreclaimable offender. ..... I suspect that a small number of executions ..... would do more to check crime than twenty times as many sentences of penal servitude." And again, "If society could make up its mind to the destruction of really bad offenders they might in a very few years be made as rare as wolves, and that probably at the expense of a smaller sacrifice of life than is caused by many a shipwreck or explosion." Dr. ANDERSON recognises that such a return to bygone methods is inadmissible and he is constrained to admit the futility of his own proposal. "For even," he says, "where the law authorises penal servitude for life the judges will not impose, and public opinion will not tolerate, such sentences for ordinary crimes against property. But my proposal assumes that we shall cease to regard the *punishment* of the offender as a matter of primary importance." Therefore, he

tells us, that radical changes in prison administration would be involved.

But is all this upheaval of our present system of penal legislation and administration necessary? We think not. As we have already said, we do not believe that the figures adduced by Dr. ANDERSON warrant him in arriving at the opinion he has formed as to the serious increase of professional crime. As shown in the Report of the Commissioner of Police of the Metropolis for 1899, the proportion of felonies has decreased in 20 years by fully one-half. In our opinion this decrease in felonies generally must be taken as affording satisfactory evidence that the influences at work, whatever they may be, are tending, both directly and indirectly, to bring about, and are bringing about, a decrease in the number of the more serious crimes against property and in the number of professional criminals by whom these crimes are committed. Mr. TROUP of the Home Office, the editor of the "Judicial Statistics" for 1898, makes some interesting remarks on this point. From a table dealing with the proportionate amount of crime to population he concludes that "crime would appear to have reached a maximum in the sixties, and from 1868 there is a steady decline in the total and a steady decline also in the two leading divisions, crimes against the person with violence and crimes against property without violence." Further on, and dealing with what is the very basis of Dr. ANDERSON'S argument, this authority speaks as follows: "There is good reason to believe that relatively to the number of crimes committed the number of persons committing crimes is smaller in 1898 than in the earlier years of the table. It has been pointed out that in recent years there has been a great reduction in the ordinary length of sentences; that offences which used to be punished by five or seven years' penal servitude are now often punished by a few months' imprisonment, with the result that an habitual criminal after a few months of incarceration is again set at liberty and allowed an opportunity of committing fresh depredations. This is not a question of the deterrent effect of the sentence—of whether long or short sentences have the greater efficacy. We have to do merely with the fact that if a considerable number of the crimes of habitual criminals which were formerly punished by penal servitude are now punished by short imprisonment the number of offences appearing in the statistics in the proportion to the number of persons engaged in committing them must necessarily be greater than formerly; or conversely, if the number of offences has decreased the number of offenders must have decreased in a still greater proportion." This decrease must be referable to the complicated machinery which, in recent years, has been continuously at work upon criminal and criminally-disposed persons in prison and out of prison—a machinery which has reference not merely to the effect produced by imprisonment, but to the results of early education and training in the lower grades of social life, to prisoners' aid societies, and to increased opportunities for obtaining work on release from prison, as well as to other influences brought to bear upon the individuals as well as upon the class. We think that it is one of the mistakes that Dr. ANDERSON has made in formulating his proposal that he has brought severity of sentence and reduction of professional crime into a too close and absolute contiguity as cause and effect. No doubt, of late years, public sentiment has been influenced by LOMBROSO and his disciples with their fertile imaginations and their attractive, if unpractical, theories on criminology, and *pari passu* mild sentences are given which appear to be out of proportion to the crimes. But so long as crime generally is decreasing steadily the public will not be persuaded that their system of dealing with it is either absurd or wrong, or that the machinery at work is ineffective, or that there is evidence to justify them in reverting to the more Draconian measures of bygone days.

Quackery and the Law in the United States.

MR. PURRINGTON of the New York Bar recently delivered a lecture before the Church Congress at Providence, Rhode Island, upon "Eddyism and the Law," attaching the name of Mrs. EDDY, the original promoter, to the fad known as Christian Science, in preference to using the usual designation of a rigmarole neither Christian nor scientific. Eddyism, although it has been responsible for more than one death in England, has not yet assumed, and does not seem likely to assume, the numerical importance which it has in the United States, so that the principal interest to the English medical practitioner in the lecture of Mr. PURRINGTON lies in his exposition of the laws generally prevailing in various American States under which endeavours have been made to control the irresponsible pretence of healing on the part of persons wholly unqualified by education and training. In the case of DENT *v.* Virginia (129 United States Reports, 114), to which he refers, the question for the decision of the Supreme Court was the validity of a statute of West Virginia requiring every person practising medicine in the State to obtain a certificate from the State Board of Health as to his possessing certain defined qualifications. It was objected on behalf of a practitioner not so qualified that this statute violated a constitutional principle governing all legislation in the United States to the effect that no individual State may deprive any person of life, liberty, or property without due process of law, but it was held that the State, in the exercise of its power to provide for the general welfare of its people, may exact from parties before they can practise medicine a degree of skill and learning in that profession upon which the community employing their services may confidently rely; and the statute of West Virginia was upheld. This statute, however, or statutes of similar tenour, will not always avail to prevent the dangers of Eddyism and similar crazes. It does not need the astuteness of a lawyer to see that to a charge of illegal practice of medicine a denial of *any* practice of medicine may be held a good answer. That the defence has been actually made, and made successfully, we find in an instance cited by Mr. PURRINGTON, in which it was said by the court that "Prayer for those suffering from disease, or words of encouragement, or teaching that disease will disappear and physical perfection be attained as a result of prayer, or that humanity will be brought into harmony with

God by right thinking and a fixed determination to look on the bright side of life, does not constitute the practice of medicine in the ordinary sense."

In another American case (SMITH v. LANE, 24 Hun. 632) a defendant set up in defence to an action by a masseur for his fees that the masseur was a medical practitioner, but that not being duly qualified as such he was not entitled to recover. The defendant lost his case, for the court naturally declined to regard the masseur as a medical practitioner, but awarded him the fees due to him as a masseur. The court also incidentally gave its opinion that statutes regulating "medical practice"—using that term without further qualification—were intended to forbid incompetent or unqualified persons from administering or applying medical agents or performing surgical operations, in order to prevent injury and loss of life resulting to those employing such persons. This dictum strengthens the position of the Christian Scientists, inasmuch as this sect makes no use of medical agents and expressly repudiates operative surgery. We find, however, from Mr. PURRINGTON that in one State, that of Nebraska, the statute relating to medical practice defines a medical practitioner as "anyone who shall operate on, or profess to heal or prescribe for, or otherwise treat, any physical or mental ailment of another." This definition of medical practice can clearly be made to work against Eddyism. Under it an Eddyite was held to have been rightly convicted of acting as a medical practitioner without having complied with prescribed conditions, the New York Supreme Court holding that "the object of the statute is to protect the afflicted from the pretensions of the ignorant and avaricious and its provisions are not limited to those who attempt to follow beaten paths and established usages."

It will be seen from the instances cited by Mr. PURRINGTON that the law regulating medical practice in America varies in form in different States, and cannot be described as certain in its results. It is interesting, however, to observe what has been attempted in a country whose legal system closely resembles our own even if it forces us to the conclusion that legislation against quackery must always be attended with the greatest difficulty. No country approves of legislation in defence of class interests, while day by day the difficulty of setting verbal boundaries to the limits of medicine becomes greater. Again, differences of opinion naturally exist as to those against whom legislation should be aimed, which would have to be settled before definition was attempted. For example, as far as we know, the elder of the Peculiar People does not practise for gain, and some may hold that only those who profess to heal for gain should be interfered with. Again, the old woman who prescribes simples for a cold in the head or who charms warts can hardly be said to be such a danger to the community as to be a fit subject for legal interference. There is, moreover, a strong feeling in Great Britain against anything which seems to interfere with liberty of thought and action. But with regard to this we may fairly point out that to legislate for the protection of the ignorant is recognised as the duty of the Government in other cases, even where the person protected would probably claim to be a free agent acting upon his own judgment and entering into a contract which primarily concerns himself. Only recently, for example, the business of usury has been placed under a stringent Act of Parliament. The business of those who trifle with the health and life of foolish people is at least as fit an object for State interference as that of those who lend money to foolish people at exorbitant rates of interest. That life and health are now trifled with, and this with impunity, is shown by the avoidable deaths which have taken place through Eddyism, through the ignorant fanaticism of the Peculiar People, and through quackery. We recently drew attention to a case where a herbalist attended a patient till she died from cancer, prescribing such mixtures for her use as his wife might dictate when in a hypnotic trance. Such mischievous mystics ought to be restrained by law.

It is difficult to quit the subject of Christian Science without referring to its amusing side. Mr. PURRINGTON tells us that Mrs. EDDY, although teaching that "there is no such thing as pain or disease and that she can restore decaying bones to a healthy condition," has had teeth taken out under the application of local anæsthetics by a dentist, whose name and address he gives. She now, it appears, wears false teeth made by the same gentleman. Mr. PURRINGTON also quotes the following delightful piece of etymology from her religious writings: "The word pantheism is composed of two words, Pan and Theism. Pan stands for a deity in mythology; theism for a belief concerning deity in theology." No wonder that she adds warningly, "The mythical deity may please the fancy, while pantheism suits not at all the Christian sense of religion." We wonder what the erudite Mrs. EDDY would find to say about a "Pan-Anglican Synod," or how she would define the functions of her mythical deity in a "Pantechnicon."

Rex v. Browning.

WE publish in another column a letter from Mr. GIDEON W. B. MARSH giving the history of this remarkable case. The defendant, CHARLES WILLIAM BROWNING, aged 35 years, was indicted at the County of London Sessions before Mr. MCCONNELL, K.C., chairman, for having made false statements with intent that they should be entered in the register of deaths contrary to the provisions of the Registration of Births and Deaths Act, 1874. It appears that the prisoner had been a medical student and in this way had become possessed of the requisite knowledge to skilfully make a counterfeit presentment of disease. The whole story is so interesting to medical men as to demand a little commentary.

On Jan. 14th, 1901, BROWNING called upon Mr. MARSH complaining of difficult micturition. He paid him another visit on Jan. 25th. Four days later Mr. MARSH was fetched to the prisoner's lodgings. He found the patient with a temperature of 103° F. saying that he had pains in the loins and constant headache. BROWNING also said that he was passing urine frequently and in small quantities. The urine was of the colour of porter, specific gravity 1025, and on microscopical examination showed hyaline and granular tube-casts. Mr. MARSH diagnosed the case as one of acute

nephritis. On Feb. 4th the albumin, which had been in considerable quantity, had materially increased. The man was collapsed and apparently in a rigor. The following day he was very drowsy and had convulsive movements in the limbs; altogether he was confined to bed for eight days. On Feb. 6th an individual called on Mr. MARSH and said, "At four o'clock my brother had a fit, in which he died," giving a description of uræmic convulsions. Mr. MARSH thereupon issued a certificate wherein "uræmia consequent upon acute nephritis" was given as the cause of death. The suspicions of the prisoner's landlady were aroused by the fact that the "brother" had not called in anyone at the death, that the body was locked up in the room, and that no one had been to lay it out. Mr. MARSH proceeded to the house to verify the death. On gaining admission to the presumed death-chamber he found a dummy corpse. The police were communicated with and eventually the prisoner was arrested, being himself patient and "brother." In a box in his room was found a policy on the Pearl Life Insurance Company for £200. BROWNING, whilst Mr. MARSH was attending him, had worn a heavy moustache. The "brother" was clean-shaven, and so completely had the operation changed his appearance that neither the medical man nor the landlady was aware of the deception that was being practised upon them. It was quite natural that there should have been a resemblance between the physiognomy of two brothers. The moustache was the differential object which masked their identity. We cannot help regretting that the law interfered with BROWNING'S disposal of the "corpse." We feel defrauded of the last chapter of the story. The difficulty in the way of effecting the burial, as a body, of some rolled-up blankets and a pair of boots was the only rational corroboration of the prisoner's statement that he obtained the certificate to convince his relatives that he was dead. He might have intended to abscond after he had obtained the death certificate and registered it, or he might have had designs upon the Pearl Life Insurance Company, though this impeachment he denied.

The story forms a remarkable instance of malingering, probably with a substratum of real disorder; of mistaken identity of the living; and of attempted pretence of death. It is not stated whether BROWNING'S temperature was taken in the mouth or the axilla. If in the latter we may imagine that he had taken measures to produce evidence of pyrexia, though he declared that he had not done so but was genuinely feverish. Natural illness which BROWNING said he suffered from may have accounted for the collapse. On the other hand, both it and the drowsiness may have been produced by toxic agents. It would be interesting to know whether any of the symptoms persist. The albumin in the urine was, according to the prisoner's statement, surreptitiously added, and the blood can obviously be accounted for in the same way. It is not so easy to account for the hyaline and granular tube-casts. Either the man was the actual subject of Bright's disease, the symptoms of which he had exaggerated even to feigning death therefrom, or else some urine from a nephritic patient had been substituted for his own and given to Mr. MARSH for analysis. We are of opinion that Mr. MARSH is blameless for having fallen into the trap laid for him. More, he is to be complimented for the dexterity with which he extricated himself from it. We entirely subscribe to his contention that it should be a legal duty not only to certify the cause of death but also to verify the fact of death.

Annotations.

"Ne quid nimis."

MEDICAL APPOINTMENTS TO THE KING.

THE King has appointed Lord Lister to be Sergeant-Surgeon-in-Ordinary to His Majesty and Sir William Mac Cormac, Bart., K.C.V.O., and Sir Thomas Smith, Bart., Honorary Sergeant-Surgeons to His Majesty. We are glad that His Majesty has decided not to allow these historic appointments to fall into desuetude. The following appointments have also been made. To be Honorary Physicians: Dr. D. McEwan, Inspector-General (retired); Sir James J. L. Donnet, K.C.B., Inspector-General of Hospitals and Fleets; Sir John Watt Reid, K.C.B., Director-General of the Medical Department of the Navy (retired); Dr. A. B. Messer, Inspector-General of Hospitals and Fleets (retired); Dr. H. C. Woods, M.V.O., Inspector-General of Hospitals and Fleets. To be Honorary Surgeons: Sir James Jenkins, K.C.B., Inspector-General of Hospitals and Fleets; Timotheus J. Haran, Inspector-General of Hospitals and Fleets; Sir James N. Dick, K.C.B., Director-General of Medical Department of the Navy (retired); Dr. William H. Lloyd, Inspector-General of Hospitals and Fleets; and Dr. Alfred G. Delmege, M.V.O., Deputy Inspector-General of Hospitals and Fleets.

THE DENTAL HOSPITAL OF LONDON.

IN March the new premises of this hospital in Leicester-square will be occupied. They have been constructed in thorough accordance with modern requirements. The old hospital has long proved to be utterly inadequate for the vastly increasing needs of the charity, and the ample accommodation provided, together with the modern equipments, will be accordingly appreciated. Probably if the freehold of the old site had not been obtained the acquisition of the new premises and building would have been further delayed, much to the detriment of the educational progress of the institution as well as of its real philanthropic work. But owing largely to the munificence of Sir Edwin and Lady Saunders some years ago, together with the substantial help of many members of the dental profession, the freehold of the old site was obtained, and it now proves a valuable asset. The new hospital will therefore start with an ineffaceable debt to Sir Edwin Saunders and his wife. But the growth and progress of this important department of charity are a credit to all the staff and the students. From the commencement of the rehousing and rebuilding scheme to the present time they have contributed no less a sum than £15,450, in addition to £2000 which, as we announced last week, were recently given by the staff—facts which afford an example of self-help that should stimulate the giving of help from without. As the authorities are still appealing for funds it is well that the present financial position in regard to the new hospital should be known. When it was decided to build a new hospital the site upon which it is now erected in Leicester-square, adjoining the older hospital, was in the market. It was decided to purchase this site, and members of the medical and dental professions and patrons of the old hospital subscribed several

thousands of pounds in response to an appeal. At that time the houses upon the site yielded rents which it was intended should help to defray the expenses of building new premises. Soon after the negotiations were completed, however, the London County Council and the vestry decided that the houses were unsafe, so that they had to be pulled down. The rents thus ceased. The managing committee were then faced with a serious problem. Two courses were open to them—either to sell a splendid site or to retain it, costly as it necessarily was, in such an excellent position, and finally to mortgage it and the building when finished. The bankers of the hospital, Messrs. Barclay and Co., came to the aid of the committee and promised to advance the money at 4 per cent. to build on condition that the building was mortgaged on completion and their advances were repaid. The result of this is that the site and hospital buildings are mortgaged for £55,000, at 3½ per cent., to be paid off in 30 yearly instalments with interest, unless large donations or legacies enable the sum to be paid off more rapidly—a contingency which is happily provided for in the mortgage deed. It is to be hoped that generous donations and subscriptions may be forthcoming, in order that the committee of management may be speedily relieved of all anxiety on this score. There can be no doubt that the institution is in the highest sense deserving of support, and hitherto its claims upon the public have, in our opinion, not been sufficiently considered. The administration of a dental hospital involves considerable expense. The staff of the Dental Hospital of London consists of 17 dental surgeons and 11 anæsthetists, all of whom are honorary officers giving up several hours a week to the work. A deserving patient can get extractions with or without anæsthetics and teeth stopped free of cost on presenting a governor's order; while crowns, bridges, and dentures are supplied on payment of small fees partially to defray their cost. It is hoped that these charges will be abolished in future years; they will be abolished if the financial position of the hospital improves as its work becomes better known.

ARSENICAL BEER IN LANCASHIRE.

WE have received a copy of the report of the medical officer of health of the Lancashire County Council, Mr. Edward Sergeant, in which the extent reached by the beer-poisoning epidemic in that county is well and briefly described. The investigation was commenced as soon as it became known that the hospitals of Manchester and Salford were getting crowded with patients suffering from symptoms attributable to peripheral neuritis, and that the origin of the epidemic had been traced to the consumption of arsenically contaminated beer. From Nov. 27th to Dec. 3rd, 1900, inclusive, 78 preliminary samples of beer were taken and of these 27 contained arsenic. Subsequently a letter was sent to the medical officers of health of the various districts affected warning them of the probability of the sugar being used in the manufacture of beer being contaminated with arsenic. Replies were received, showing that patients suffering from symptoms characteristic of chronic arsenical poisoning had been recognised in several districts, and that altogether 372 cases had come under observation. Subsequently to the issue of this circular letter addressed by Mr. Sergeant to the various medical officers of health of the county, and down to Jan 8th, 1901, 141 samples of beer were analysed, of which 31 were contaminated with arsenic, the largest amount found being equal to three-fourths of a grain per gallon, or more than a maximum medicinal dose per pint of beer. It is, however, satisfactory to note that more recent analyses have shown that the beer supplied to the country districts has improved in character. That the evil has not yet passed away is evident from the fact that two of the samples purchased on Feb. 8th have each been found to contain one-tenth of a grain of arsenic per gallon. Recent inquiries have elicited that generally the patients suffering from the effects of poisoning are improving or have recovered. Some, however, Mr. Sergeant adds, are still seriously ill from the effects of arsenic taken in beer 10 or 12 weeks ago.

THE PERILS OF AN ASYLUM MEDICAL OFFICER.

THE dangers to which asylum medical officers are exposed are well exemplified by the sad case of Dr. Margaret Orange, the assistant medical officer of the London County Council Lunatic Asylum at Claybury. During the year 1899 she was assaulted by lunatics under her charge, being struck behind the ear and also knocked against some iron railings. Leave of absence was granted to her in order that her health might be restored, but so far, we regret to learn, she has not recovered. She was in receipt of salary and emoluments amounting to some £270 per annum, but it now seems likely that she will never be able to earn her living. On Feb. 12th the Asylums Committee of the London County Council recommended that Dr. Orange should be granted a pension of £100 per annum, and this recommendation was adopted by the Council on Feb. 19th. The pension dates from Jan. 24th, 1901. We offer our sympathy to this brave lady upon the cutting short of her career and express our hope that she may yet at some future time be enabled to continue her professional work.

THE HEALTH OF HAVANA UNDER AMERICAN RULE.

MAJOR W. C. GORGAS, United States chief sanitary officer of Havana, has just issued his report upon the hygienic conditions prevailing in that city during the past year. Yellow fever, the disease which is most dreaded by persons of white race inhabiting or visiting Cuba, is shown by the report to stand eighth in the records of deaths for the year. In 1899, the first year of American occupation, there were 103 deaths from yellow fever in the Cuban capital, the lowest number in 10 years, while in 1896 the death record from the same cause was 1282. In 1900 seven diseases caused more deaths than yellow fever in the following order—tuberculosis, 851 deaths; diarrhœa and enteritis, 506 deaths; organic diseases of the heart, 443 deaths; meningitis, 395 deaths; diseases of the arteries, 357 deaths; malaria, 344 deaths; and pneumonia, 319 deaths. Typhoid fever, diphtheria, small-pox, and other epidemic diseases caused comparatively small mortality. There were a considerable number of fatal cases of tetanus. In the 12 months covered by the report 1244 cases of yellow fever occurred, 920 of which were among Spaniards with a death-rate slightly above the average death-rate for the city, which was 24·90. Among the Americans there were 235 cases. Of all cases about two-thirds had been in Cuba less than one year, the large majority being recently arrived Spanish immigrants. The immigration has been very large, the last four months of the year giving a little more than 11,000. The report declares that the effect of the measures adopted for ridding Havana of the foci of infection has been very marked. Of the 857 occupied blocks making up the city 452 have had one or more cases of yellow fever in them. In these blocks are 26,701 houses; 885 have shown evidence of infection by having had one or more cases. Of the 885 infected houses 694 were successfully disinfected by one disinfection, as shown by the fact that they had only one case; 130 required two disinfections, that is, of the 885 infected houses all but 61 were freed from yellow fever after the second disinfection. These results

demonstrate the success of careful isolation and prompt disinfection. Of the 24,000 immigrants into Havana during the year 21,000 came from Spain, which fact explains the large proportion of Spaniards among the cases of yellow fever. In 1900 Havana had a smaller number of deaths than in any one of the preceding 10 years; 1893 was next with 6697 deaths, some 500 more than last year. The average number of deaths for the 10 years up to 1900 was 10,243. Last year there were 4000 less than this average. The death-rate for 1900 was 24·40, while the lowest of the preceding 10 years, 1893, was 30·66, and for the first year of the American occupation, 1899, it was 33·67. It is noticeable in the list of deaths that a large proportion of the fatalities occurred among white males. This is due to the fact that a large portion of the population of Havana is composed of foreigners, and these foreigners are almost entirely white males, the male population of Havana greatly outnumbering the female. The report ends by saying that it is not too much to state, judging from results, that the measures, sanitary and otherwise, which have been taken by the American authorities with a view of improving the health of Havana have been most eminently successful. This work has reduced the death-rate of 1898, the last year of Spanish rule, from 91·03, which represents 21,252 deaths, to 24·40, representing 6102 deaths; and the methods pursued have caused a steady improvement in the sanitary conditions of Havana. Taking the average number of deaths per year for the 10 years at 10,243, which would be for the two years 20,486, as representing what the deaths would have been if the United States had not interfered in Cuban affairs, and deducting from this the actual number of deaths (14,255) which have occurred in the two years of the American occupation, we have 6231 as the number of lives saved in the city of Havana by the efforts of the American authorities. Too much stress must not, of course, be laid upon such calculations and deductions, but it is undoubted that the United States are to be congratulated upon some sterling sanitary work.

THE LUMBAR INJECTION OF COCAINE AS AN ECBOLIC IN THE INDUCTION OF LABOUR.

A CORRESPONDENT recently[1] laid before our readers a summary of American and continental observations of the value of lumbar sub-arachnoid injections of cocaine in surgical practice. We desire now to call attention to the communications of M. Doléris to the Académie de Médecine, to the Paris Society of Obstetrics and Gynæcology, and, lastly, on Feb. 11th to the Medico-Chirurgical Society of Paris. In these communications M. Doléris confirms what had been recognised as the physiological action of cocaine on blood-vessels and on muscular tissue, and in addition to its already proved analgesic properties he refers to its ecbolic powers, or, as he terms them, its *action ocytocique*. As regards the uterus, M. Doléris maintains that this power of exciting muscular contraction may be a counter-indication of cocaine when version has to be performed, although Kreis has published a case of podalic version by the Veit-Smellie method after a lumbar injection of cocaine. M. Doléris points out that three independent observers, Kreis, Dupaigne, and himself, have now published over 100 cases of the effect and value of cocaine in labour. The anæsthesia persists while the uterine contractions are strong and succeed each other rapidly, the cervix dilates regularly and quickly, and the condition of the child is excellent. These effects were further proved on Oct. 8th, 1900, when M. Doléris performed Cæsarean section for contracted pelvis in a case in which analgesia was obtained by the injection of one and a half centigrammes of cocaine into the lumbar sub-arachnoid space. The result was strikingly satisfactory, the uterus remaining firm and contracted after the extraction of the child and while the uterine sutures were being applied. In no previous Cæsarean section had M. Doléris observed such thorough and prolonged uterine contraction. In uterine inertia the effect of the injection of one centigramme (about one fifth of a grain) of cocaine is similar. Finally, M. Doléris attempted successfully to prove that such injections sufficed to provoke uterine contraction apart from all natural commencement of labour. He has given details of two cases of induction of labour by means of the injection of the small dose of one centigramme of cocaine. In the first case a patient was sent to him with the correct diagnosis of a seven months pregnancy, the fœtus being dead and macerated. The patient was kept in hospital for three weeks under observation. The cocaine was then injected and 15 minutes later the uterus, which had been inert and limp for about a month, contracted regularly and vigorously for one and three-quarter hours without arousing any pain. The os uteri was then of about the size of a five-franc piece. As the analgesia passed off the uterine contractions became less powerful and labour continued normal, being completed in six hours and 20 minutes. This comparative rapidity may be noted in contrast with the slowness of dilatation in most cases of macerated fœtus. In the second case the onset of labour was even more rapid. The patient, a multipara pregnant eight months and one week, was *in extremis* with advanced tuberculosis. Nine minutes after the injection the uterus contracted vigorously, the pains following each other every three minutes, the labour being completed in four and a half hours. M. Doléris thus maintains that the spinal injections of cocaine act with certainty on the motor nerves of the uterus and form a new method of inducing labour, and that they are of great value in the treatment of uterine inertia. He has had no accident in 78 cases. A considerable amount of confirmatory evidence must be forthcoming before these observations of M. Doléris can be accepted as holding good in all cases. One of the main objections hitherto urged against the use of lumbar injections of cocaine in midwifery is that the drug tends to produce uterine inertia and abolishes the action of the abdominal muscles. It is a pity that the records of cases of parturition treated in this way do not give us fuller details upon this important point. It is a striking fact that in 40 cases Marx had recourse to the use of forceps in no less than 16, a very high proportion. M. Doléris's present contention is the more striking since in quite a recent communication he advocated the dilatation of the vagina and perineum by the use of hydrostatic bags as a means of hastening delivery in cases of labour in which analgesia had been produced by lumbar injections.

[1] THE LANCET, Jan. 12th, 1901, p. 137.

DISINFECTION OF THE HANDS.

As was recently stated in these columns[1] the results obtained with Schleich's *Wachsmarmorstaubseife* by several observers were all more or less contradictory, and that not only with regard to the claims of the inventor himself but also *inter se*. It occurred, therefore, to Dr. Deeleman to inquire into the matter, so that the question might be set at rest once for all, and accordingly he instituted a series of experiments with the discredited preparation and has recorded his verdict in the *Deutsche Militär ärztliche Zeitschrift*. The conclusions arrived at, although in some respects at variance with Schleich's assertions, are, nevertheless, on the whole in favour of the efficacy of the compound, which the investigator pronounces to be "a remarkable means of disinfection for the hands." It is absolutely necessary, however, that before using it the nails should be cut as short as possible and also that every

[1] THE LANCET, Oct. 27th, 1900, p. 1220.

endeavour should be made to clear out all fissures and furrows, whether natural or artificial, and to render the skin of the hands as soft, smooth, and pliant as possible. In order to prepare Schleich's "mechanical disinfector" 750 parts of resinous soap (clear yellow in colour, freshly made, and cut up into small pieces), having been dissolved in 1500 parts of hot water, should be placed upon a fire with 150 parts each of stearine and wax. As soon as the last-named substances are melted 700 parts of powdered marble should be poured in very slowly, the mixture meanwhile being carefully stirred. The loss from evaporation (usually about 300 parts) should next be made good and then boiling be allowed to continue until the mixture becomes of the consistency of syrup, the last part of the process generally lasting about half an hour. As soap produced in this way is said to cause slight epidermic erosions in tender skins it would be prudent to avoid making use of it in laboratories where preventive serums of an infectious disease were being manufactured.

SPECIAL OPHTHALMIC NUMBER OF THE "INDIAN MEDICAL GAZETTE."

IN the January number of the *Indian Medical Gazette* it is announced that a special Ophthalmic Number will be issued in a few months. Everything will be done to make this forthcoming number representative of ophthalmic surgery in India at the present day, and circulars have been sent by the editor to ophthalmic surgeons throughout India inviting information on points of interest in connexion with diseases of the eye and its appendages, and especially on the subjects of cataract, trachoma, and errors of refraction. The replies to these circulars are to be addressed to Major W. J. Buchanan, I.M.S., Editor *Indian Medical Gazette*, Bhagalpur, E.I. Railway, or to the Editor, *Indian Medical Gazette*, care of Messrs. Thacker Spink and Co., Calcutta. On account of the great field for ophthalmic operations which exists in India our contemporary's collective investigation cannot fail to be of practical importance and will form an interesting contribution to ophthalmological literature. Last year the same journal brought out a special number devoted to the treatment of stone in the bladder, allusion to which has already been made in our columns.[1]

CREASOTE IN PNEUMONIA.

IN a paper read before the Central Texas Medical Association Dr. J. L. Van Zandt drew attention to the advantages to be obtained by the use of creasote or preferably creasotal in pneumonia. After giving his own experience, which he said was satisfactory, Dr. Van Zandt quoted several passages from the writings of other physicians, all speaking highly of this method of treatment. Dr. Van Zandt spoke in enthusiastic terms of the results he had obtained. At first he gave one drop of the drug every three hours, but latterly he had prescribed seven and a half minims of creasotal. This appears to be a large dose, but he states that "others give larger doses with possibly better results or no harm." He adds: "I have had cases in which the fever was gone in from 24 to 48 hours, and I am now somewhat disappointed if my patient is not ready for dismissal by the third or fourth day." In conclusion, Dr. Van Zandt expresses his opinion "that the use of creasote or carbonate of creasote in the treatment of pulmonary inflammation is one of the greatest life-saving discoveries of the century just ended." We cannot adopt Dr. Van Zandt's extremely laudatory attitude towards creasote, but in some affections, notably of the gastro-intestinal tract, it is undoubtedly a most useful drug. At one time it was extensively used in pulmonary tuberculosis, but is now not nearly so frequently employed; indeed, many authorities consider that its great advantage in cases of tubercle is not due to any selective action in the bacillus of tuberculosis, but to its preventing fermentative changes in the digestive tract, thereby greatly improving the power of digestion or absorption of food. With regard to its use in pneumonia we prefer to suspend our judgment. The recognised treatment of this affection is mainly expectant—to preserve the patient's strength as far as possible and to endeavour to lower the temperature should it continue raised too long. We think that creasote might be tried in this country more extensively than it has been, for the evidence brought forward by Dr. Van Zandt is certainly strong.

[1] THE LANCET, Jan. 19th, 1901, p. 193.

MILK-SUPPLY AT ASHTON-UNDER-LYNE.

AT the last meeting of the town council of Ashton-under-Lyne an important step was taken towards reducing one of the factors contributing to the high infant mortality so discreditable to our manufacturing districts. The sanitary committee have been recommended to purchase "two 'Wyvern' sterilisers complete, one milk receiver, one measuring and mixing tub, two cream cans, one bottling machine, one 3-h.p. boiler, and other apparatus." A shop is to be taken for sterilising and humanising milk, and a competent manageress is to be obtained. Mr. Shaw, in moving the adoption of the minutes, contended that the proposed scheme was closely related to the question of the infant death-rate, and the committee had adopted what they believed to be one of the best schemes in the country. The milk is to be called "modified," not "humanised," and it is to be sold not only in bottles for infants' food, but in pints and quarts for general use. The whole of the medical profession in the town are said to support the scheme. Mr. Shaw anticipated "that eventually it would become a source of profit." Indirectly it will almost certainly become profitable by diminishing sickness and lowering the death-rate, provided that it is efficiently carried out and made use of by the people, and we may wish for it every success.

PUBLIC HEALTH IN THE STRAITS SETTLEMENTS.

THE estimated population for the whole of the Straits Settlements for 1899 was 604,916, as compared with an estimated population of 592,587 for 1898. The number of births registered during 1899 was 14,537, and the number of deaths registered was 19,150, giving a birth-rate of 24·03 per 1000 of the population and a death-rate of 31·16 per 1000. In his "Annual Medical Report on the Straits Settlements Civil Hospitals for the year 1899," Dr. Max. F. Simon, the principal civil medical officer, says that small-pox was the only epidemic disease prevalent during the year, over 300 cases occurring in Singapore. The whole number of admissions to hospital during 1899 was 22,835, and the number of deaths was 3432. The five diseases under which the greatest number of admissions to all the hospitals was returned in 1899 were as follows: venereal diseases, 2523 (with 88 deaths); malarial fevers and cachexia, 2336 (with 148 deaths); beri-beri, 1793 (with 589 deaths); rheumatism (acute and chronic), 1137 (with two deaths); and dysentery, 913 (with 313 deaths). The hospitals in Singapore of which statistics are given are the General Hospital, the Prison Hospital, Tan Tock Seng's Hospital, the Leper Hospital, the Lunatic Asylum, and the Maternity Hospital. In Singapore the highest shade temperature for the year was 88° F. in May and the lowest was 71° in February. The total rainfall was 103·36 inches. A small outbreak of plague which happened in Penang during May, June, and July is reported on by Dr. T. S. Kerr, the colonial surgeon. There were 49 cases, including 46 Chinese, one Malay, and two Tamils; 39 died. A large proportion of

the seizures occurred in brothels and 19 of the Chinese patients were females.

BRITISH CONGRESS ON TUBERCULOSIS.

AT this congress, which is to be held in the Queen's Hall, Langham-place, London, W., in the week beginning July 22nd, 1901, it has been arranged amongst other matters for three public addresses to be delivered in the arge hall on Tuesday, Wednesday, and Thursday of that week. The first will be given by Professor Koch of Berlin, the second by Professor Brouardel of Paris, and the third by Professor J. McFadyean of the Royal Veterinary College.

CLINICAL SOCIETY OF LONDON.

ON March 8th the Clinical Society of London will hold a discussion at 20, Hanover-square, W., on the recent epidemic of enteric fever among the troops in South Africa. It will be opened by Dr. Howard H. Tooth with a paper on Some Personal Experiences of the Epidemic in the Orange River Colony. It is understood that Sir William Church, Sir Dyce Duckworth, and Professor A. E. Wright of Netley will speak at the meeting. The principal points to be raised by Dr. Tooth in his paper will be as follows:—1. The origin of the epidemics: In the camp at Modder river; relation of the Bloemfontein epidemic to that of Modder river. 2. The dissemination of the disease: (*a*) Water: At Modder river camp (the Modder, the Riet, and wells); at Bloemfontein (the spring, wells, and latterly the waterworks). (*b*) Sandstorms. (*c*) Flies. (*d*) Personal infection from man to man. 3. Precautions taken to prevent the spread of the disease: boiling and filtering of the water; the sinking of wells; latrine arrangements, the disinfection of evacuations. 4. Preventive inoculation: figures relating to patients admitted to the Portland Hospital; inoculated and non-inoculated compared in respect of severity of symptoms and mortality; general remarks on inoculation; probable value of the reaction as a measure of natural immunity. 5. Some remarks on treatment. It will be seen that Dr. Tooth's paper deals with matters that are of exceptional interest just now to the public as well as to the medical profession.

CASES OF SPINA BIFIDA TREATED AS OUT-PATIENTS BY OPEN OPERATION.

IN the present issue of THE LANCET we publish an account of three cases of spina bifida in the cervical region which were under the care of Dr. James H. Nicoll in the out-patient department of the Glasgow Royal Hospital for Sick Children. Dr. Nicoll treated them all, as he has treated many others, by the open operation and then sent the patients home to be looked after by their mothers. In all the cases the wounds healed by first intention, and the patients recovered completely and remained well. At the present time much more serious cases are treated in the out-patient department than formerly and this is chiefly to be attributed to the practical certainty of the asepsis of modern surgical wounds The advantages of a mother's care of a child are not to be denied, and in Dr. Nicoll's cases there was the safeguard of the superintendence of hospital sisters who visit at the patients' homes and see that the nursing is carried out satisfactorily. Without venturing to criticise the practice of treating cases of spina bifida as out-patients—for the results attained by Dr. Nicoll may be reasonably claimed to justify the method—yet we may point out that there is no region of the body in which sepsis is so fatal as it is in the brain and spinal cord, and that therefore a displacement of the dressing might easily prove fatal. The supervision by the hospital sisters of the nursing in the home goes far to obviate the risk of the occurrence of this danger, but it does not entirely remove it. It would be of interest to have a list of all the cases which Dr. Nicoll has thus treated. Such patients can, of course, be treated as well at home as in a hospital if the nursing is adequate, but that is the great difficulty experienced in dealing with patients of the class who attend the out-patient department of a hospital.

THE NEW SYDENHAM SOCIETY.

IN another column we publish a letter from Mr. Jonathan Hutchinson to which we would direct our readers' earnest attention. Although as Mr. Hutchinson says of the New Sydenham Society, the "*raison d'être* of the society has been to a large extent removed," it has done such admirable work in the past that it would be a thousand pities if its existence were to cease. The proposed "Atlas of Pictorial Aids to Diagnosis," an advertisement of which scheme appears in our present issue and a description of which is given in Mr. Hutchinson's letter, would undoubtedly be of great value. Pictures are the books of the unlearned and all of us are unlearned in some or other department of our profession. For every one of us there exists some disease or condition which he has never seen but which at any time he may be called upon to diagnose. The present membership of the New Sydenham Society is nearly 1400. To make the new scheme a success at least 2000 members are required. We trust that the additional 600 members will be obtained.

A LEAGUE AGAINST HOOLIGANISM.

THE Twentieth Century League held an inaugural meeting at the Mansion House on Friday, Feb. 22nd. The influential character and considerable size of the meeting show how deeply the object of this league—viz., to remedy the neglect that has led to the present condition of disorder among the young portion of the community in and around London—affects the public interest. That a condition of grave disorder largely exists none can doubt who reads a daily newspaper. That Hooliganism, to use a convenient and inclusive expression, is an inevitable accompaniment of the growth of great cities unless special steps are taken to repress or prevent the evil is no doubt true, and that such steps have in London been hitherto inadequate is, we are afraid, equally the case. The Twentieth Century League will have the sympathy of all our readers and perhaps the active support of younger members of the medical profession whose time permits them to take a part in such enterprises as these, for which their elders can spare only the support of goodwill or subscription. Among the best institutions for carrying out the class of work which the Twentieth Century League intends to foster and extend are settlements in connexion with the Universities and the great public schools, and among the best workers at such centres there are usually to be found a sprinkling of young medical men. Their close association in hospital work with the class to whose physical and moral welfare the settlements are devoted often gives men of our profession a sympathy with, and an influence over, young men and women of the poorer classes that are not usually accorded to the ordinary man of education. Moreover, to the youths for whom cricket, football, gymnastics, or boxing are not, for one reason or other, available, a class in the rudiments of first aid to the injured is often one of the most popular occupations for winter evenings. Such classes and similar instruction for young women in the elements of nursing and care of children are usually conducted by young medical men. The chief aim of the Twentieth Century League will be to get hold of boys and girls on leaving school and provide them with means for adequate exercise and rational amusement under proper conditions. The great difficulty, judging from what we know of present institutions with a like aim, is to find a large enough number of active supporters. Here,

too, the medical profession may, by turning into a useful channel the misspent energies of many a young woman and man who suffers from having much money and no aims, benefit both their own patients and the girls and boys of the poor and general public. It is obvious that the national welfare is largely bound up in the proper evolution of thousands of poor boys and girls into men and women sound in body and mind. To insure such a future for the younger members of the poorer classes of London is the object of the Twentieth Century League and it will meet with the support of every right-minded citizen and the especial sympathy of the medical profession.

THE GOVERNMENT AND THE LICENSING LAWS.

MR. WHITTAKER'S amendment to the Address led to a speech from the Home Secretary which goes far to remove the impression of indifference or helplessness on the part of the Government left by his previous speech to a deputation. We wait hopefully for the promised Bill. All other countries are alive to the importance of the drink question and neither the violence of faddists nor the interests of political parties ought to be allowed to interfere with reasonable legislation.

THE POOR-LAW MEDICAL SERVICE OF THE HIGHLANDS AND ISLANDS OF SCOTLAND.

WE have received a copy of a petition which the Poor-law medical officers of the Highlands and Islands of Scotland have addressed to the House of Commons asking the consideration of the House for the onerous and unfair conditions under which they hold office. The petition points out that the Local Government Board of Scotland have no powers to deal with the grievances complained of without further legislation. The board, for example, cannot ensure proper holidays for the medical officers by providing that the parish councils shall pay for substitutes to do the work during the absence of the medical officers on vacation, though the board has expressed its sympathy with such a reform. The Poor-law medical service of Scotland does not compare favourably with the similar services in England and Ireland, as we have pointed out often in our columns. In Scotland parish councils have the power to dismiss their medical officers with a few weeks' notice and without a reason, whereas in England and Ireland the approval of the respective Local Government Board of the country has to be obtained. The medical officers of the Poor-law districts in Ireland have been conceded the right to an annual holiday of reasonable length, the parish councils or boards of guardians being empowered to pay for qualified substitutes. No such just treatment has been extended to the medical officers of the poorer districts of Scotland. The medical officers of the Highlands and Islands of Scotland receive salaries which are completely inadequate to the work that is demanded of them, while the rise in the fees of locum tenents places any idea of their availing themselves of such services out of the question. The petition prays that the same fixity of tenure should be afforded to the Poor-law medical officers in Scotland as is afforded to Poor-law medical officers in England and Ireland; that during an annual holiday of reasonable length a substitute should be paid by the parish; that during illness contracted or accident met with in pursuance of professional duty the parish council should pay a substitute, or alternatively should insure the medical officer against sickness or accident; that a free official residence should be provided for the parish medical officer, an adequate salary, and a satisfactory superannuation allowance. There is not a word in this most reasonable petition which does not meet with our heartiest support. We have on previous occasions dwelt more upon the necessity of the tenure of these posts being fixed than upon other points, but to grant the medical officers fixity of tenure in posts where their arduous work is rewarded with no vacations, no pension, and little salary, is not a conspicuous kindness. We trust that the House of Commons will find time to right the grievous wrongs of the Poor-law medical officers in the Highlands and Islands of Scotland. The petition only asks for what is just.

UNCERTIFIED DEATHS.

A DEPUTATION from the General Medical Council had an interview on Thursday last on the above subject with the President of the Local Government Board. The deputation consisted of Sir William Turner, Sir Dyce Duckworth, and Dr. J. G. Glover. The Registrar-General, Dr. Tatham (Superintendent of Statistics at the General Register Office), and Mr. Power (Principal Medical Officer to the Local Government Board) were also present.

DRUG HABITS IN THE UNITED STATES.

THE New York School of Clinical Medicine has established a special department of neurology, of which Dr. T. D. Crothers of Hartford, Conn., has been elected professor—viz., the study of the neuroses and psychoses of alcoholism and of drug habits. Dr. Crothers is announced to deliver immediately a course of clinical lectures on inebriety from alcohol, opium, chloral, cocaine, and other narcotics. These lectures appear to be timely, for the diseases dependent upon or associated with the abuse of alcohol, opium, chloral, cocaine, and other narcotic drugs are steadily increasing in the United States of America, and the demand for special treatment in institutions and retreats is becoming more pressing every year. The last number of the *Quarterly Journal of Inebriety* has the following words in a leading article: "All the large public hospitals and asylums in the States have wards and rooms for alcoholics and drug-takers, and the same demand for treatment is seen in private practice in the increasing number and urgency of such cases." It is also important to notice that there is practically very little special literature dealing systematically and authoritatively with the nature and treatment of these neuroses. As a consequence this field is largely occupied by charlatans and irregulars, who, with innumerable specifics and secret drugs, claim the most marvellous results. We hope that the departure of the New York School of Clinical Medicine, in giving exact systematic instruction in these diseases, will be welcomed by the medical profession in the United States.

THE Executive Committee of the General Medical Council publish the following analysis of the voting at the election recently held in Ireland of a Direct Representative to be a member of the Council for the ensuing five years.

Total number of voting papers issued ...	2759

IN our Manchester correspondent's letter last week reference was made to the memorial which it is proposed to establish of the late Professor Tom Jones. To-day we print in another part of THE LANCET a letter from the supporters of the movement together with a list of some of the contributions already promised. As it is desired that all who participate in the proposed tribute to the deceased

professor's memory should do so from the dictates of their hearts there will be no canvassing.

AT a meeting of the Council of Owens College held on Feb. 20th Mr. R. B. Wild, M.D., M.R.C.P. Lond., M.Sc. Vict., was appointed, subject to the approval of the court, Professor of Materia Medica and Therapeutics. The late Dr. D. J. Leech held the chair for 19 years with great benefit to the medical school and the council decided that his name shall henceforth be associated with it, so that the professorship will be called the Leech Professorship of Materia Medica and Therapeutics.

THE Society of Apothecaries of London have presented an address to the King expressing the Society's sincere condolence on the death of the late Queen "after a reign without parallel in history," congratulating the King upon his accession, and praying "that your Majesty's reign may be a long and happy one, and that every blessing may attend your Majesty and your Royal Consort, Queen Alexandra."

A TELEGRAM from the Governor of the Cape Colony, Sir Alfred Milner, to Mr. Chamberlain, received at the Colonial Office on Feb. 21st, states that the bubonic plague report for the week ending Feb. 16th notifies a total of 20 cases, the patients being one European and 19 coloured people. There were also three deaths and 104 "contacts," all coloured people.

A TELEGRAM from the officer administering the Government of Mauritius to Mr. Chamberlain, received at the Colonial Office on Feb. 22nd, states that for the week ending Feb. 21st 16 fresh cases of plague occurred, 10 of which were fatal. The total deaths from plague amounted to 13.

THE Goulstonian Lectures of the Royal College of Physicians of London, the delivery of which was arranged for March 12th, 14th, and 19th, are, owing to the illness of the lecturer, postponed to a later date, of which due notice will be given.

UPWARDS of £600 have already been subscribed towards the erection at Norwich of a memorial statue to Sir Thomas Browne.

HISTORY OF RENAL SURGERY.

BY DAVID NEWMAN, M.D., F.F.P.S. GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

I.

THE classification of diseases of the kidney into surgical and medical was, not more than 15 years ago, questioned as being an arbitrary one, but now that the arrangement is accepted, the importance of a knowledge of renal surgery is fully recognised by the profession, and its special study is placed in the position to which it is entitled by the great advances which have been made during the period mentioned. Without invading the sphere of the physician the surgeon has come to his assistance and at the same time extended his own field of operation. But in order that the best results may be attained the physician and the general practitioner must work hand in hand with the surgeon, and endeavour to recognise the cases at an early stage in the disease that are likely to be benefited by surgical treatment. Only by such cöoperation can the highest achievement be gained.

Seeing that it is one of the internal organs that is affected the patient naturally looks to the physician for relief. The medical attendant who makes an early diagnosis renders to the patient a service as valuable as that of the surgeon who at a later date performs a successful operation. Doubtless many diseases of the kidney are difficult to diagnose in their incipient stages even after careful analysis of the symptoms and physical signs; therefore, anyone who desires to form a correct diagnosis, with the view to operative interference, must be familiar with the very intimate relationships existing between the various parts of the urinary system. In other words, the surgeon must not only be thoroughly acquainted with his own special department, but he must also have a knowledge of that sphere which has been conventionally assigned to the physician.

Although conceived at a very remote period in the history of our art, the birth of renal surgery, as we now know it, cannot be placed at a more distant date than 30 years ago, and therefore it must be regarded as one of the youngest branches of surgical outgrowth. Its early conception and its very slow development cannot fail to be of interest to those who have witnessed its rapid and vigorous growth in our own time. A study of the early history of the subject will show how far the highly developed surgery of the present day is indebted to the thought and labours of the ancient apostles of the healing art. Their early efforts are not now well known, and therefore have not been fully appreciated in our time. It is remarkable how much information can be gathered from a study of the writings of eminent physicians in the remote past. They, like the observers of the present day, gained their knowledge from practical experience with the phenomena of disease; they showed wonderful perseverance in collecting facts, in separating truth from error, and with these faculties they combined an extraordinary ability for generalising and or enunciating principles, and a power of publishing them *virum volitare per ora*. Francis Adams of Banchory, in Aberdeenshire, a man of great learning and most conversant with ancient medical lore, who translated from the Greek the seven books of Paulus Ægineta, as well as the works of Hippocrates, remarks in his preface (1833):

> It appears to me that, at certain periods of ancient times, the standard of professional excellence was such as would not easily be attained at the present day, with all our vaunted improvements in knowledge; and that many of those early masters of our art were distinguished for varied stores of erudition, an ardent love of truth, and an aptitude to detect the fallacies of error, such as few of us even now can lay claim to.

While their opportunities were hampered by a lack of the exact scientific knowledge and the methods and the means of investigation which we now possess, the acuteness of their observations is surprising, and their descriptions of symptoms, their prognoses, and their indications as to treatment are so clear that the individual diseases can now be easily recognised and placed in our nomenclature. Hippocrates (B.C. 460), who is rightly regarded as the "father of medicine," held that to become an eminent physician it was not only necessary for the student to cultivate an acquaintance with the structures and functions of the human subject, but also to be skilled in logic, astronomy, and the other sciences. 2000 years before Europe gave John Locke, philosopher, philanthropist, and physician, the credit of introducing the methods of inductive philosophy into this country, and before the great learning and superior judgment of his friend Sydenham advanced medicine, Hippocrates studied and taught according to the same strict principles. He says:—

> The physician must be able to tell the antecedents, know the present, and foretell the future—must meditate these things, and have two separate objects in view with regard to diseases—namely, to do good or to do no harm. The art consists of three things, the disease, the patient, and the physician. The physician is the servant of the art, and the patient must combat the disease along with the physician.

Hippocrates mentions diseases of the kidney in many passages of his works, and he recommends incision to be made in cases of abscess in order to furnish an outlet for the pus. It has been a matter of dispute whether Hippocrates advised the incision of the kidney or simply the evacuation of perinephric abscesses, but as abscesses of the kidney are much more common than collections of pus around the organ, the probability is that the earlier operations were performed for pyonephroses, and that in some instances calculi also were removed. In his treatise on internal affections four diseases of the kidneys are described.

> Four diseases originate in the kidneys. Under the first the patient suffers in the following way, violent pain arises in the kidney, the groin, and in the testicle of the same side. A frequent discharge of urine changes to stoppage; with the urine sand is discharged, which causes violent pain. After the discharge the pain ceases, and then returns in like manner. During the discharge of urine the pain is sometimes so severe that the patient has to rub the penis. Many doctors who are not acquainted with this disease think, when they see

the sand, it must be a vesical calculus, but this is not the case; it is more likely to be stones in the kidney. This disease is caused by mucus which the kidneys absorb, but do not give out again, and thus small stones like sand are formed. In such a case perspiration should be caused by the root or juice of Scammony, but an aperient must first be given. The following day another aperient should be given, administering at the same time a drink composed of 2 measures [equal to 7 litres] of a decoction made from chick-peas and salt. After this the patient should be treated with regard to drinks, food, and baths, as in a case of *strangury*, and the same medicines should be used. During the attacks of pain the patient should be bathed frequently and warm poultices applied. If however, a swelling should arise, it will be necessary to cut into the kidneys, remove the matter, and take away the sand by means of diuretics. After cutting, there is a chance of recovery, otherwise the disease generally ends in death.

Under the second disease, the pain is as violent as in the first case The suffering begins after great bodily exertion, which tears the small veins leading to the kidneys, and causes the latter to fill with blood. If this happens, the patient passes blood with the urine and afterwards matter. If the body is allowed to rest, recovery will be quick; on the other hand if it is moved ever so slightly the pain will last much longer. If the kidney fills with matter, a swelling will appear near the spine. Under such circumstances, the swelling must be cut, and if possible deep towards the kidney. If this succeeds there will be almost immediate recovery, but if unsuccessful, there is the danger of an abscess forming which will require longer treatment. Should the abscess close, the hollow in the kidneys will fill with matter. If the latter breaks through and goes off by the anus, there is hope of recovery; but if the other kidney be drawn into sympathy, there follows great danger of death. The same medicines, treatment and diet should be observed as in the foregoing case. The diseases are dangerous, and many fall, in the end, into phthisis of the kidneys.

Under the third disease, the urine resembles the bray of roast beef. The pain is caused by the black gall flowing into the small veins leading to the kidney, which causes ulceration of the veins and kidney. Matter is mixed with the urine. Immediately there arises pain in the groin, the bladder, the perinæum, and even the kidneys themselves. It soon relaxes, returning again violently, often going into the stomach Under these circumstances Epithymum or Scammony root should be given. If the pain lasts, and there is strangury, frequent warm bathing and poultices should be applied. Prescribe a drink made from boiled wheaten flour and honey, also a soothing diet, giving Mendes Wine with honey, or other sweet white wine suitably diluted. The disease does not easily give way. According to the time of year give whey or milk, the former till purgative action takes place; the milk cure, however, is continued for 45 days. Under this treatment the disease will be cured.

The fourth disease arises from the gall and mucus, chiefly in summer time, and also after sexual excess. The patient feels pain in the side, in the groins, and in the inguinal region, and in the muscles; he cannot lie on the healthy side, suffers fearful pain, and feels as if something were torn in the side. The feet and ankles are always cold, urine is passed with difficulty on account of the mucus, and if the urine is allowed to stand, a sediment is left like flour. If gall predominates the urine is slightly red, and if mucus, white and thick. The symptoms may last a year, and suffering during that time becomes more acute. If a swelling appears during suppuration, it should be cut. A purgative and warm baths should be given in the treatment of the disease, and the patient should be kept warm.

The first class here is easily recognised as renal calculus associated with repeated obstruction of the ureter, and with transitory hydronephrosis or pyonephrosis, while the second is a clear description of rupture of the kidney from severe strain or injury. The likelihood of an abscess following a traumatism is also fully recognised, and its prognosis and treatment clearly indicated. The third and fourth classes are not so easily recognised and are probably descriptions of infective renal diseases associated with vesical and urethral disorders.

While Hippocrates certainly advocated incision in certain cases it is evident that the practice was not followed by the ancients, and the Arabian writers only casually refer to it. Celsus, who lived and taught at the beginning of the Christian era, condemned operations upon the kidney, and this opinion prevailed almost universally until our own day. This retrogression from the teaching of Hippocrates undoubtedly retarded any progress in renal surgery. Celsus, who flourished during the reign of Augustus, writing on diseases of the kidney associated with hæmaturia and pyuria, is by no means clear in his descriptions and it is difficult to be certain if he distinguished between the symptoms of renal calculus and of stone in the bladder. He, however, paid attention to injuries and contusions of the kidney.

Ruffus Ephesus,[1] who lived in the time of Trajan, is one of the oldest writers on diseases of the kidney. He was probably prior to Galen (A.D. 130), and perhaps to Aretæus (A.D. 120) and certainly to Cælius Aurelianus. Francis Adams in his translation of Paulus Ægineta[2] says regarding Ruffus:—

As we have seldom occasion to meet with him in our researches, we shall give a fuller abstract of his opinions on this subject than we would otherwise have done. The symptoms of inflammation of the kidneys, as detailed by him, are pains below the loins, so that the patient cannot stand erect nor walk, but it obliged to lie upon his back, which position affords him most relief; the pains extending to the bladder and testicles; the extremities cold, more especially the legs and feet; frequent and painful desire to make urine, which is at first thin and watery, but afterwards becomes redder. These symptoms are followed by emaciation of the thighs and hips, debility of the limbs, and sometimes suppuration. His treatment is as follows: The patient is to be laid on a soft couch, and must abstain from food for one day, but long abstinence is forbidden. If the bowels require to be opened, this is to be done by means of emollient clysters, such as injections of hot water, decoctions of mallows, of linseed, or of fenugreek, to which may be added some oil. Large injections, however, are forbidden, lest they press upon the kidneys and occasion irritation. When the bowels are evacuated, and yet the pain does not remit, the parts may be wrapped in wool which is smeared with hot oil having rue, marsh-mallows, dill, or mugwort boiled in it. When the pain is acute, a vein at the elbow is to be opened after which emollient cataplasms and plasters are to be applied to the back when the kidneys are affected, and to the fore parts when the bladder. When these remedies fail to remove the pain, the loins and groins are to be cupped, and then sponges squeezed out of hot water are to be applied, and the patient put into a hip-bath of hot water in which poppies, chamomile, and the like have been boiled. Then, when the patient is laid in bed, let him be fomented with bladders half-filled with oil and water; and afterwards let cerates of the oil of privet, &c., or fragrant malagmata be applied. When the pain is excruciating, he directs us to give a decoction containing opium and the heads of poppies. In due time diuretics are to be administered, such as the root of acorus, ground-pine, cassia, spignel, parsley, sea urchins, radishes, carrots, and the like. When an abscess is formed, there is a discharge of tawny and more natural urine, there is swelling in the loins, strong heat in the kidneys, and the pain becomes duller with irregular fever. The abscess bursts either into the bladder or intestines. Praxagoras, he says, related a case in which there was pus voided by the anus for twelve years and probably longer. When it bursts into the bladder, pus is voided with the urine. Suppuration is to be promoted by frequent fomentations with sponges, by cataplasms of barley-meal with a decoction of figs in mead or wine, to which may be added pounded wormwood, spurge, &c. For promoting the rupture of the abscess, diuretics are prescribed, such as wild marjoram, mock dittany, and the like. When the abscess does not burst, acrid clysters containing black hellebore, radishes, garlic and the pulp of colocynth are to be given. To these oil may be added, and when thus taken they will promote the rupture of the abscess. However, fomentations with sponges and plasters are to be applied to alleviate the pain. When the ulcers are of a mild nature (which is shown by the abatement of the fever and pain, and from the substances which appear in the urine being white and inodorous), the milder diuretics are to be used for cleansing them, such as the seed of pompion, the decoction of dates, &c., or, when stronger things are required, galbanum, opopanax, turpentine, rosin, and the like may be added to mead or wine. When the ulcers are putrid, Æthiopian cumin with must, rue with honey and wine, and the like may be given internally; while cataplasms of bitter vetches boiled in wine and honey are to be applied externally. It is proper also, he says, to inject some of the medicines for dysentery, to give clysters of strained ptisan; and to place the patient in hot water. If the matter is thick, a decoction of fennel, parsley, or wormwood is to be given. With respect to food, he recommends milk, especially that of mares or asses, along with honey; also cucumbers, lettuces, the flesh of kids, lambs, and goats, almonds, and wine; but vinegar must be avoided. All motion is to be abstained from. When there are symptoms of repletion, emetics are to be given. When the abscess points outwardly, he seems to direct us to open and apply the cautery; but here unfortunately the text is incomplete.

Galen[3] (A.D. 130), who is looked upon by his admirers and followers as the *beau idéal* of an accomplished physician, and who is copious enough on diseases of the kidney, especially upon stone, does not refer to operations on the kidney as a means of treatment. In the "Isagoge," which is generally ascribed to Galen, he explains that calculus is due to viscid humours which have been much heated, and the heat acts upon them as on clay, rendering them hard and insoluble. He describes a case of bleeding from the kidney in a patient who fell, and without injuring his spine sustained a rupture of the kidney. After a preliminary hæmaturia the urine ceased to flow, and when a catheter was passed, while the instrument was blood-stained only a little urine escaped, showing that there was obstruction to the ureter and suppression of the excretion. He believed in internal rather than in external treatment, and in the matter coming away by the natural passages. This opinion was held until the eighteenth century, and it hindered also the further development of surgery.

This (he says) may of course cause ulceration and therefore great care must be taken in the healing. If this does not take place rapidly, it becomes serious. The continuation of ulceration is easily recognised. The patient has pain in the kidney, passes matter as from an ulcer, and at the same time little pieces of skin, and then blood appears in the urine.

Haly Abbas,[4] who wrote during the early part of the tenth century, says that old men are more subject to renal calculus, for in them the watery part of the urine passes down to the bladder, while the more solid material is retained in the kidney, and there forms a concretion, with heat of the part and a viscid humour. Rhases, upon the authority of Antyllus, who wrote after Galen and prior to

Oribasius (A.D. 360), states that calculi are due either to drinking turbid water or to imperfect digestion.

Aëtius[5] (sixth century) gives a full exposition of the views of the ancient physicians and furnishes very exact details regarding treatment. He shows that abscess of the kidney is very liable to lead to fistula, and that it is difficult or impossible to heal. He indicates some of the causes of bleeding from the kidneys: "According as it arises in those who have lifted a heavy weight, or have jumped vigorously, or fallen from a height, or undergone some other similar violent shock."

During the dark ages the physicians satisfied themselves by learning what the Greek and Arabian authors taught until through time they came to believe that Hippocrates, Galen, Ptolemy, and Aristotle had finally settled all scientific questions and that to doubt their decisions was heresy. Respecting operations on the kidney Galen's teaching was believed in rather than that of Hippocrates or Ruffus, and consequently the surgical treatment of suppurative disease of the kidney dropped into obscurity. Little advance was made in the pathology of renal disease until the seventeenth century, when the practicability of operating upon the kidney again came to be discussed. The subject was approached, however, at that time more from the philosophical than from the scientific standpoint; later, pathological anatomy furnished new means of research.

(To be continued.)

AD TERRAM.

BY SIR FRANCIS SEYMOUR HADEN, F.R.C.S. ENG.

THE EARTH AND THE SOIL.

I HAD hoped, after the record which you were good enough to enable me to make in THE LANCET of May 27th, 1899, p. 1411, of my views as to the competency of the earth, properly treated, to deal effectively and harmlessly with all forms of organic decay returning in the course of nature to its surface, that I should not again have to trouble you on the subject; nor should I be doing so now if continued investigations had not satisfied me that we hold in our own hands a key to other equally great truths which in our engrossing pursuit of the microbe we have allowed to escape us—a key, also, which, if applied with a firmer faith in the ordinary operations of nature than we seem just now disposed to accord them, I would fain hope may one day win us back to those larger methods of Inductive Research which we associate with the name of Bacon, and to which, indeed, we owe, directly or indirectly, nearly every great discovery that we have made our own since his time.

It is, however, not alone to regret our growing tendency to break away, on grounds which I must think wholly speculative, from the surer methods of the Baconian philosophy, that I am again venturing to address you, but rather to invite the attention of the profession to the experiments we are making and the language we are employing to chronicle their results—experiments which, since we are making them not in the earth, but in the soil which covers the earth, do nothing to prove the latter the hotbed of infection which some would have us believe it to be, but rather suggest one of two things—either that we are failing to recognise the real nature of the medium we are employing in our investigations, or, which is even more likely, that we are taking it for granted that the soil and the earth are one and the same thing, whereas, from the point of view of the present article, not only are they not the same thing, but, in all but the equal and independent share which they have in the conversion of effete organic matter into its elements, two essentially different bodies—different in their origin, different in their nature, and different in the parts which they play in the world's economy.

Nor is there, I would respectfully submit, any room to doubt the prevalence of the additional oversight which we are thus making, since evidence of that tendency confronts us at every turn—in our choice of the soil as a medium in which to make our experiments, a medium in which we may, if so minded, cultivate anything from a microbe to a mushroom; in the adoption of a terminology, fast degenerating into a vernacular, which is intelligible only to those of us who are content to live under the exacting dispensation of the microbe; in our lectures, our correspondence, our reports, and even in our text-books, which, one and all so far as I can see, speak of the earth as a sort of composite body which they describe as "the soil," or it may even be, when put to it for a pseudonym, as the "subsoil." Thus, we are in no way surprised when so accurate an observer as Professor G. V. Poore[1] candidly tells us that when he speaks of "earth" he means "humus" (which *is* soil), or when so practical and conscientious an experimentalist as Dr. Klein[2] uses the term "earth" in the same sense as his equally careful fellow-reporter, Dr. A. C. Houston,[3] uses the word "soil"; or finally, since it is useless to recapitulate examples of the same thing, when my courteous critic and mentor, Sir Charles Cameron of Dublin[4] referring to "gravels and boulder clays" (which are *earths*) calls them "soils," and even goes out of his way to emphasise the kindly lesson he is reading me, by a formal record of his belief that "the cleaner the soil we live on the longer we shall live on it." But the soil which I am speaking of is never clean, never has been clean since the globe became populated, and never will be clean till it reverts to the sterility which there is every reason to believe at one time affected it.

The soil, in fact, according to experiments which have been now uninterruptedly carried on at Woodcote for 14 years, and which, though still incomplete on one or two points, I consider fully warrant the crude results I am now giving of them, *is* "soil" in the most ordinary acceptation of the word—organic refuse, that is, animal as well as vegetable, which having lived its life and served its purpose on the outermost confines of the globe has dropped out of existence and, in obedience to a law which neither it nor any other material body is able to resist, is already when we meet with it on its way towards its centre of gravity. Soil, in fact, according to my understanding of it, is *manure*—the very medium in which with so much confidence we are making our experiments—the one great fertilising agent without which the earth would starve, its populations die out, and the atmosphere itself—deprived as it would then be of its means of renewal and consequently without a purpose—not impossibly also cease to exist.

The earth, on the other hand, properly so-called (from my point of view), is the very opposite of all this. While the soil is organic the earth is inorganic. While the soil has its origin on the periphery of the globe, the earth has its origin in its own centre, and its earliest developments in the breaking up and gradual disintegration (by a variety of forces, the nature of which being well understood I need not here dwell upon) of its own primitive rocks, till at last they are reduced to the friable matter which we know as "earth." Again, as to the comparative age of the two bodies; while that of the soil can in no case exceed the age of the animal which produces it, or in the case of vegetables the duration of the seasonal intervals which mark the rotation of crops, the fall of the leaf, and so forth, the age of the earth is measurable only by the countless ages during which we know it to have been in course of formation. And yet, again, separated as the two bodies originally are by a space as great as that which separates the poles from the equator, and approaching each other—as, in a sense, they may be said to do—from opposite ends of the earth, they have, and can have, nothing in common till by a provision of nature (gravitation) they are brought into actual contact; a contact differing in nothing, so far as I can see, from that of any two bodies which, being chemically incompatible, give rise on their admixture to a change of their elements, and it may even be to the creation of a new force—such a force, for instance, as has its analogue in the production of the electric spark by the contact of the opposite poles of the voltaic pile. For the interposition of the microbe in changes and metamorphoses of this kind I must confess that I can see no necessity whatever, or, in fact, for that of any foreign body, saprophytic, bacterial, or otherwise cryptic and gratuitous.

The physical properties of the soil, again, its weight, its

volume, and its extraordinary value as a fertilising agent, will, from what has been said of its nature and origin, be readily understood to be measurable only by the whole extent of the earth's surface (which it more or less entirely covers and overlies) and by the amount of organic life, animal as well as vegetable, which is its immediate source of supply. Then, as to its weight and the pressure which it exercises on the earth's surface (as to which I shall have more to say later) it is, of course, that of the atmosphere *plus* its own density and the weight represented by the pressure which it exercises on the earth's surface as the effect of gravitation. It is, however, its vast extent, its kind, and the irregularity of its distribution which, for the purposes of this communication, chiefly concern us

Experiments made in the laboratory have, meanwhile, told us nothing on these points, and herein must be my apology for the nonconformity of my views with those of the eminent men who—taking the microbe for granted and making it the basis of their inquiries—have been generally received as authorities on that part of the subject; the difference between us, however, depending, I think, mainly on the fact that while their investigations have for the most part been founded on experiments made within doors, and on the strength of pre-arranged lines of inquiry, mine have been made wholly out of doors and on lines suggested simply by what I have met with and seen there during a continuous succession of observations which have engaged much of my attention for 25 years and pretty nearly the whole of it for the last 14 years.

So much for a theory merely in outline and as yet with such proofs only of its stability as may reasonably be read between the lines of the present communication. Nothing will be easier than, at the proper time, to multiply such proofs, at all events to the extent of largely extending and strengthening the ground on which that stability rests. On the other hand, points have yet to be cleared up which, though by no means obscure, require time for their elucidation, and which make me unwilling to go to print with them till I have had that time at my disposal. A single example of such points will suffice to explain this indisposition on my part. Though I have long been aware that nitrification is a more rapid process than I once believed it to be, I had no idea till lately how much more rapid a process it really is; nor, though I have now no doubt of the fact, have I yet been able to arrive at anything like its exact measure.

Again, though I have been making my graves under various conditions as to depth and the contiguity of their contents with the earth enclosing them—beginning with a depth of four feet, as that prescribed by the Local Government Board, and ending by simply laying the body on the ground and covering it over with a single foot of earth—my examinations of the whole of these graves have only been made once a year and the results of such examinations only recorded in print once a year; I now know that if I had examined them every half-year I should have found, I will not say the same astonishing results, but evidence of a far more rapid progress towards a return of the body to its elements than I had then believed possible, as well as arrived at a more exact knowledge of the rate and kind of change undergone by the body in the interval.

The solution of such a moot point is, of course, of the highest practical importance, and I am led by it to the conclusion that, rather than present such a point in an imperfect form, I shall do well to let the present paper go to press as it is and return to it later.

THE NEW OPERATING THEATRE FOR THE ROYAL INFIRMARY, PRESTON.—The new theatre which by the generosity of Dr. R. C. Brown, of Preston, has just been completed and equipped at a total cost of £2654 is in many respects a model building. It is situated in the centre of the infirmary blocks and is built of iron, glass, and tiles. Every precaution has been taken to dispense with corners and angles and the building is so constructed that it can be effectively cleansed with a hose. It is surmounted by a double roof in order that an equable temperature may be obtained at all seasons of the year. The theatre is well lighted by electric light and there is a specially large north window eight feet wide and six feet high. Nothing that could be done has been left undone to make the new operating theatre, of which Preston must be proud, as perfect as possible from every point of view, and the inhabitants of that town owe a deep debt of gratitude to Dr. Brown.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 575.)

II.

PART III. of the Commissioners' report is taken up with a detailed investigation of the various complaints made as to the care of the sick and wounded during the campaign and the conclusions arrived at in respect of such complaints. The subject is studied in the following order as regards the care taken and the various complaints which have arisen, Natal and all places not in Cape Colony, the Orange River Colony, or the Transvaal being excluded from consideration here.

(A) At the front, including some places which are conveniently dealt with under this head, such as Kimberley, Modder River, Driefontein or Abram's Kraal, Bloemfontein, Kroonstad, Johannesberg, and Pretoria; (B) in the conveyance of patients to and from fixed hospitals on the lines of communication and at the base; (C) at the hospitals on the lines of communication; and (D) at the hospitals at the base, including the hospital transport ships. .....

A.—AT THE FRONT.

The details of this class group themselves and can be best dealt with under the following heads:—(1) the advance of Lord Methuen to the relief of Kimberley; (2) the advance of Lord Roberts to Kimberley and to Bloemfontein; (3) Bloemfontein during Lord Roberts's stay there before his subsequent advance and afterwards; (4) the advance from Bloemfontein to Kroonstad; (5) Kroonstad; (6) Johannesberg and the advance from Kroonstad; (7) Pretoria; and (8) concluding remarks as to the care of the sick and wounded at the front. Outside these groups there are but few matters relating to the condition of affairs at the front which require attention beyond our general observations in Part II., and so far as these few matters appear to us to need special mention we have dealt with them at the end.

The present article only deals with the first three sections of sub heading A, the hospital question being, as all our readers know, particularly acute at Kimberley.

METHUEN'S ADVANCE TO KIMBERLEY.

With regard to A (1) the Commissioners say that Lord Methuen began his advance to Kimberley on Nov. 22nd, 1899. Between this date and Dec. 11th there were four severe engagements, ending with the disastrous one at Magersfontein, all of which were productive of many wounded. Lord Methuen's force, according to the evidence of Surgeon-General Wilson, was accompanied by the full complement of bearer companies and field hospitals, each with a complete equipment, and before the advance Surgeon-General Wilson was told by the chief of the staff that the advance was only for the relief of Kimberley, which being accomplished the force would immediately return to its base. After the battle of Belmont, however, the principal medical officer, recognising the serious state of matters, telegraphed for some of the staff of No. 3 General Hospital and got up tents and equipment. No. 3 Stationary Hospital was sent up to De Aar and after Magersfontein two hospitals of the nature of stationary hospitals were established at Orange river and Modder river. These hospitals, which were more on the scale of field hospitals, were for a short time insufficiently supplied with certain articles such as bed-pans, and there was a shortage of orderlies. The hospital trains, however, soon took the wounded down to Cape Town, so that there was never any considerable degree of pressure. The army remained at Magersfontein for two months—namely, from Dec. 11th, 1899, to Feb. 11th, 1900.

ROBERTS'S ADVANCE TO KIMBERLEY AND BLOEMFONTEIN.

Lord Roberts left Ramdam on Feb. 12th, 1900, and Kimberley was relieved on Feb. 15th. Cronje's flight and eventual surrender at Paardeberg took up the time from Feb. 16th to Feb. 27th. The advance to Bloemfontein commenced on March 6th and after fighting at Poplar Grove and Driefontein Bloemfontein was reached on March 13th. What happened during the advance from a medical point of view was as follows:—

When the advance of Lord Roberts's force for the relief of Kimberley was contemplated it was obvious that success depended on the mobility of the column of relief, and in order to ensure mobility the transport had to be reduced to a minimum. The force was very deficient in mules and forage. The ordinary allowance for moving a division is 1666 mules and 416 oxen, whereas all the transport animals available for this column during its advance at this time were 946 mules and no oxen, and only four days' forage was available for the horses, mules, and oxen for the force. Sufficient forage even for the cavalry and mounted infantry could only be obtained by reducing the daily allowance from 12 lb. to 8 lb., and of course the force had to provide for

carrying food and ammunition for the column as the line of communication was threatened. Food and ammunition were of necessity the first things that had to be considered. A minimum of 12 days' food for the army alone could be collected and carried. Under these circumstances the military authorities had to take steps to cut down the ordinary transport of the column and they found it necessary to do so rigorously, even to the extent of leaving the ordinary baggage of the column behind at Modder river and the men had to advance without any change of clothing. Amongst other transport to be cut down was that of the bearer companies and field hospitals. Accordingly the ambulances for the bearer companies were cut down from 10 to two and the transport wagons for the field hospitals were cut down from four to two, a water-cart being added because of the difficulty of obtaining water during the march. The order under which this was done is dated Jan. 29th, 1900, and is set forth in the Appendix (*vide* Appendix—*Bedford* 4). As the wagons to the field hospitals had to carry all the tents, blankets, waterproofs, buckets, &c., as well as the medical and surgical necessaries, the effect of this order upon the condition of the field hospitals was of course serious, though no doubt the two wagons left with each field hospital were loaded up to their utmost capacity by essentials, and tents and heavy materials of secondary importance were the items which were chiefly left behind, the evidence showing that requisites—such as drugs, dressings, splints, &c.—were taken in very nearly sufficient quantities. We have also already pointed out that the unit allowance of field hospitals had been greatly reduced—namely, from nine or 10 to six per army corps. The three infantry divisions engaged in the operations in the advance on Bloemfontein—namely, the 6th, under General Kelly-Kenny; the 7th, under General Tucker; and the 9th, under General Colville—were each supplied with the brigade field hospital alone, the divisional field hospital in each case not being available. In the operations at present under consideration the sick and wounded were, therefore, through the absence of the divisional field hospitals in three infantry divisions, deprived of the services of 12 medical officers, three quartermasters, and 105 men, and also of the field hospital equipment necessary for the treatment of 300 patients.

Even the *personnel* of the bearer companies and of the field hospitals was not maintained at its full strength during the advance, inasmuch as a few officers and men had to be left at Kimberley and at Jacobsdal.

Surgeon-General Wilson, when the advance to Kimberley was contemplated, was consulted as to the cutting down of the transport. When the matter was broached to him he said that he could not carry out the medical arrangements for the advance with less than the minimum of transport allowed by the army regulations, but afterwards, when the position of affairs was explained to him, he recognised the military necessity and accepted the decision of the Commander-in-Chief, as, indeed, he was bound in duty to do.

It follows that the advance had to be undertaken with the ordinary provisions for the sick and wounded gravely reduced. Nothing but military necessities would have justified the reduction. It is not for us to question the decision of the military authorities, but we may say that we are convinced that the necessities justified the step taken by them and that the suffering thereby occasioned was part of the price that had to be paid for success in the campaign. When the advance to Kimberley was commenced, it was, of course, not known for certain by the military authorities what might follow. It was considered as most probable that after Kimberley was relieved the column would be again in touch with the railway, and that the railway could be used for conveying the sick and wounded to the stationary and base hospitals. But the unexpected movement of General Cronje's army, and its pursuit, changed the nature of the campaign. The British army had to pursue, and then followed the remarkable advance which resulted in the surrender of Cronje's force at Paardeberg, and the advance to and capture of Bloemfontein. That advance had to be made under the conditions as to field hospitals, bearer companies, and transport already indicated. The transport originally allotted to the field hospitals and the allowance of ambulances to the bearer companies could not be increased during the advance, for, owing to a convoy being attacked by the enemy, the advancing army lost three days' supply of food. As it was not known where the army might ultimately have to go, or, if it went to Bloemfontein when that place would be reached, all available transport had to be utilised for the purpose of bringing up food and ammunition to the army. When Paardeberg was reached, communications were opened with Kimberley, and in that way sufficient food was obtained for the army to allow half rations being given to the troops. Up to Paardeberg the only way of dealing with the sick and wounded was by sending them back by ox-wagons which had been emptied of food, to Modder river or Kimberley. These wagons are of necessity rough, and the suffering occasioned by the journey in them over the veldt to many of the patients must have been severe, especially on cold nights, as the men were in their summer clothing with no change, and but few extra blankets could be obtained.

The stationary hospital at Modder river was only intended to act as a base hospital for the advance to Kimberley, but as a matter of fact, owing to the unexpected movement of General Cronje it became one of two base hospitals employed in the first part of the advance on Bloemfontein. Kimberley was used as the second base hospital for this advance. During this time it is admitted that a general hospital at Orange river would have relieved the strain considerably.

Major Bedford, with regard to this advance, says: "The work was done under considerable pressure and we should have been glad to have had more help; but it was not more pressure than one expects on a campaign. We should have been much more comfortable if we could have had a general hospital at Orange river."

The reasons given for failing to plant a general hospital at this point are two: (1) it was not known to the Surgeon-General that the western line—that is, the De Aar to Kimberley line—would be occupied for so long a period, or that it would assume such importance in this part of the campaign; and (2) when the troops left Ramdam the immediate objective was Kimberley and the advance to Bloemfontein which followed was unexpected.

At Paardeberg there were many wounded. For 11 days, from the 17th to the 27th February, the troops occupied a position on both sides of the Modder river in the neighbourhood, and the chief casualties occurred on the 18th February, when an attempt was made to force Cronje's position from all sides. The field hospitals were placed along the bank of the river on sloping ground on which there were some trees which afforded a certain degree of shelter from the sun. There were no houses in the neighbourhood which could be used for the reception of the wounded, and in addition to the tents there was only one stable which was available for this purpose.

Owing to the cutting down of the transport the tents were greatly reduced in number and the wounded were much in excess of the accommodation they afforded. Large numbers had to lie in the open air under the shelter of the trees. This was more particularly the case on Sunday, 18th February, when over 800 patients were brought in as a result of the action on that day. Fortunately the nights were warm, although undoubtedly much discomfort was caused by two or three wet days. Everything possible, however, was done to obviate this difficulty, and Mr. Kendal Franks in his evidence states that the engineers endeavoured to improvise shelters for the wounded men by means of branches covered by rushes.

Very important in connexion with this is the statement of Mr. Watson Cheyne. He says: "I do not think that the fact of the patients being in the open affected them a bit," and again, "I think the hardship at Paardeberg was of very little consequence." Some evidence rather conflicting with this view was given by Major Barrett-Lennard, a volunteer officer attached to the Army Service Corps. But his evidence is opposed to the evidence of several witnesses, and is, on the whole, we think, exaggerated. Still, it cannot be doubted that the treatment of the sick and wounded was carried on at Paardeberg under very great strain. Short in regard to *personnel*, short also in appliances and equipment, the powers of the Royal Army Medical Corps were taxed to the utmost. Mr. Watson Cheyne states he had a difficulty in obtaining water which had been sterilised by boiling for the operations he had to perform owing to a deficiency in kettles, and further, that he was somewhat short of dressings. This difficulty arose from the cutting down of the transport, but it was soon relieved by getting what was necessary from the stores at Modder river. Notwithstanding the pressure at Paardeberg the arrangements which were made for the comfort of the sick and wounded appear to have been satisfactory. The Rev. J. Blackbourne, an army chaplain, speaks in the highest terms of the services rendered by the medical men, and one interesting incident which he narrates (*vide* Minutes of Evidence, question 7279) renders it evident that the same treatment was given to everyone, both officers and men, irrespective of rank. Mr. Hands, the correspondent of the *Daily Mail*, likewise bears testimony to the attention which was paid to the sick and wounded. He says: "At Paardeberg I saw a good deal of the hospital arrangements because the main hospital camp lay between the head quarters, where I had often to go, and my own camp"; and he goes on to state that "the arrangements and everything were excellent ..... the men seemed to be most comfortable in their tents and quite satisfied with the arrangements."

In addition to the large number of wounded who had to be taken care of at Paardeberg, considerable sickness was developed there, partly due to the hardships of the campaign and partly to the bad water which was drunk by the troops. The sick and wounded men could not be kept at Paardeberg, for there were no tents or proper accommodation for them there, and, moreover, they could not have been supplied there, especially as the enemy were threatening the position. They had, therefore, to be sent down to Kimberley or the Modder river. The evacuation of the field hospitals to these places had to be effected rapidly.

To effect this convoys left every day and had to go a distance of about 25 miles to Kimberley or to the Modder river. Kimberley had the advantage of being able to afford house accommodation to the wounded, but this was counterbalanced by the fact that as the line of communication with the Cape was at that time broken by the destruction of the bridge over the Modder river the ambulance train could not reach it and the patients who were sent there had to remain. Ambulances for the transport of the wounded from Paardeberg were not available, the ox-wagons which were employed being those that had brought up food and other stores from the Modder river and which would otherwise have returned empty. It was during the journey of these convoys over the veldt that the hardships borne by our sick and wounded soldiers were chiefly manifest, and Mr. Watson Cheyne stated he thought that some patients had died as the result of the journey. Sad as this is, there can be no doubt that the evacuation of the hospitals was a military necessity. A stationary hospital could not have been established at Paardeberg because, as already pointed out, when the army moved on the hospital would have been left exposed to the enemy, who would in all probability have looted its stores. Every provision that was possible appears to have been made to lighten the sufferings of those carried by these convoys. Except in a few instances the convoys were accompanied by a medical officer and by orderlies. Those going to Modder river stopped at the guards' field hospital at Klip Drift. They were there fed, and their wounds dressed. The convoys passing through Jacobsdal were attended to there, the wounded men had their wounds dressed, and all had medical comforts administered to them, the worst cases being detained at Jacobsdal and attended to at the German Hospital there. Occasionally, owing to the deficiencies of staff, some of these convoys not conveying the more severe cases had to go unaccompanied by a doctor or by trained orderlies. In these cases the necessary food and medical comforts were put in charge of some responsible non-commissioned officer. We should perhaps add that at Paardeberg the difficulties of the medical authorities were increased owing to the British having to take over the care of the Boer sick and wounded, extra labour being thus cast upon the already diminished staff and field hospital equipment. It was probably owing to this that for two or three days there were insufficient dressings for some of the wounded.

KIMBERLEY AND MODDER RIVER.

As will be seen from the above statements, the pressure on the hospitals at Kimberley and Modder river after Paardeberg was very great. In one day there arrived at Kimberley 523 patients, and at Modder river also in one day 779.

DRIEFONTEIN OR ABRAM'S KRAAL.

At Driefontein there were 361 wounded, some of whom had to be left on the field all night, though this must not be taken to mean that they were unattended. Owing to lack of transport it was impossible to take the wounded along with

the army, and a hospital had to be established at Driefontein. The hospital consisted of two houses and some tents. There was no want of necessaries for the patients, and they were transferred to Bloemfontein about March 23rd.

BLOEMFONTEIN.

Bloemfontein was occupied on March 13th, the force bringing with it between 200 and 300 patients. Some 10 days after the sick and wounded arrived from Driefontein, being about 400 in number. Enteric fever broke out with startling suddenness and a very larger number of men were attacked. Three general hospitals, the Irish Hospital, and No. 5 Stationary Hospital had been got ready to be moved up as soon as the advance to Bloemfontein was determined upon. But owing to the cutting of the railway and the lack of transport the three general hospitals did not all arrive until April 29th. The Langman, the Portland, and the Irish Hospitals also arrived in April, from April 2nd to April 12th. No. 5 Stationary Hospital arrived on March 28th. Thus the field hospitals had for some time to be used as if they were and had been properly equipped as fixed hospitals, and the rest of the hospital accommodation consisted of sundry buildings in the town. There was undoubtedly for a time a deficiency in both equipment and staff.

Condition of the Town after the Advance to Kroonstad.

In the beginning of May the army began its advance from Bloemfontein towards Kroonstad. The field hospitals had then to be cleared in order to accompany the troops and their patients had to be discharged, principally into the general hospitals. As the advance continued the sick and wounded of the force were sent back to Bloemfontein, with the result that throughout May there was great overcrowding, especially in General Hospitals Nos. 8 and 9, into which practically all the patients were poured who could not be taken into the buildings or private hospitals. The private hospitals only took a comparatively small increase over the numbers for which they had been originally equipped. The effects of this influx upon Nos. 8 and 9 General Hospitals will appear when we come to deal more particularly with those hospitals, as we do later on. There were also during April, and still more during May, undoubted deficiencies of bedsteads, mattresses, commodes, bed-pans, feeding-cups, and such-like utensils, and there was a lack of hospital clothing for the patients, at any rate in the early part of May. Further, there was an insufficient number of Royal Army Medical Corps surgeons, trained orderlies, and nurses. The principal medical officer, Surgeon-General Wilson, appears to have had available in South Africa some civil surgeons to assist in the treatment of the sick and wounded; but, as already pointed out, it was not practicable to use them except to supplement the surgeons of the Royal Army Medical Corps and in hospitals in which the latter formed a substantially large part of the staff.

In June the condition of things greatly improved. The authorities were in a position to send down patients who were able to bear the journey to the hospitals on the lines of communication and at the base, and by the time this Commission arrived at the town the accommodation for the sick and wounded was more than sufficient and the patients were in every respect being well cared for.

Difficulties of Dealing with the Sick and Wounded.

Before dealing in detail with the condition of the hospital at Bloemfontein at the times when complaints have been made with regard to them, it is right that we should point out the difficulties which were in the way of the authorities in dealing with the sick and wounded in the town owing to military exigencies and the impracticability of getting sufficient hospital equipment and necessaries up from the lines of communication and the base. These difficulties are clearly set forth in the evidence given before us by the principal military authorities, and in particular in that of Lord Roberts.

On his arrival in the town Lord Roberts found himself cut off for a time entirely from his base. He had with him very little supply for his army. He had hoped to get trucks up from Naauwpoort by rail, but up to the 28th March, owing to bridges being broken, no truck could cross the Orange river, so that he was unable to obtain any supply of food for the troops except a little which he commandeered between Bloemfontein and Norval's Pont and carried into Bloemfontein by ox-wagons. The first railway truck did not arrive until the 29th March, and until then nothing could be got by rail. The food for the army at Bloemfontein alone required 40 trucks a day. Between the 29th March and the 7th April Lord Roberts was only able to obtain 286 truck-loads, and between the 8th April and the 17th inclusive only 503 truck-loads, a shortage for the month which prevented even full and sufficient food being obtained for the army. Between the 29th March and the 17th April the army at Bloemfontein had never more than one day's reserve of food accumulated, though a reserve of food was urgently necessary for a speedy advance towards Pretoria.

* * * * * * *

The care of the sick and wounded was not disregarded by the military authorities, and (speaking generally) so far as it was possible under the circumstances they transported up to the town what was required for the patients. Throughout the period of difficulty the officers of the Royal Army Medical Corps did their best to urge upon the military the necessities of their patients and the importance of providing for them, and by the 17th April there were brought up by rail into the town 62 truck-loads of hospital and medical stores and comforts and 461 truck-loads of ordnance, mostly for the sick.

We think it right to state here that the condition of things in the town in the early days would have been much worse than it was had not the railway and military authorities done such extraordinarily good work with their single line—work which stands out as especially good when it is considered how hampered they were by broken bridges and culverts, and breaks in the lines of communication made by the enemy. This is made apparent by the following short statement of material, &c., sent up to Springfontein and Bloemfontein by rail between the time of the opening of the railway to Bloemfontein on the 29th March, and Lord Roberts's advance towards Kroonstad about the 3rd May (*vide* Appendix—*Nathan*):—Truck-loads: 3684 supplies, 861 ordnance, 1138 horses, 842 troops, 118 hospital and medical traffic, 487 military wagons, 445 coal for railway, 100 ammunition, 45 railway and telegraph material, 351 baggage, 841 livestock, 87 general, 140 various, and 159 ambulance coaches; or 9298 truck-loads and ambulance coaches in all. It was owing to this good work, and only by great effort, that by the 3rd May a reserve of 45 days' food and sufficient equipment were obtained to enable the army to advance.

Notwithstanding the difficulties of transport, doctors and nurses were sent up by the authorities to Bloemfontein, but not, in the early days, as many as were required. Nurses started for the front as soon as the railway officials notified that they could safely cross the Orange river. On the 18th March a telegram was transmitted from Bloemfontein to the principal medical officer at Cape Town for 30 nurses. This was promptly attended to, for 20 left on the 19th, and 12 a few days afterwards. These were sent up even before the railway was opened and only reached Bloemfontein with considerable difficulty. By the end of March 56 nurses altogether were at work in the various buildings, 24 having been obtained locally, and the number was still further increased in April, when the principal medical officer was informed by telegram from Bloemfontein that more nurses must not be sent up for some time as there was then no more accommodation for them available. By the end of April there were 123 nurses altogether at Bloemfontein (*vide* Appendix—*Bedford* 5).

The Condition of the Hospitals at Bloemfontein.

The report goes on to consider in detail the condition of the hospitals during the periods when causes of complaint existed. The field hospitals are dealt with first and especially that of the 12th Brigade. The first half of this hospital arrived well equipped on April 4th with accommodation for 50 patients. On May 4th the other half arrived. On its arrival on April 4th the hospital had 15 double circular tents and five single tents and it took over from the 18th Brigade field hospital with their sick and wounded—

seven single tents and 22 double circular tents, the latter including one bearer company marquee. On the 26th April two more marquees were added. Being a field hospital, in its ordinary tents it had, as usual, no beds, mattresses, or change of clothing, and but few stretchers, and nurses were of course not employed. Although this condition of things was normal, it is difficult to understand, seeing the length of time that this particular field hospital was detained at Bloemfontein, and that it was used to a certain extent as if it were a fixed hospital, why beds and stuffed mattresses could not be procured or extemporised for use in the tents. As already mentioned, this hospital soon became overcrowded, and the doctors attending were too few to properly cope with the number of patients, and were overworked. In the marquees, matters were somewhat better. It was contemplated that no severe cases should be allowed to remain in the bell-tents, but that they should be moved into the hospital buildings in the town, or into the marquees. But owing, as time went on, to the large increase of sick and wounded, in some instances even severe cases had to be and were left in the bell-tents, inasmuch as room could not be obtained for them elsewhere. Some patients passed through the whole course of their illness in these tents, but such cases were neither numerous nor very severe in type. As there has been some dispute with regard to the exact numbers treated in this hospital, we may state that according to Colonel Gubbins's evidence and return (*vide* Appendix—*Gubbins* 2), the maximum number was 455, of which 247 were enteric fever cases. This maximum number was reached on the 18th May. It must, however, be remembered, in considering these figures, that this hospital received all kinds of cases. Soldiers not capable of performing their duties at the front, though not severely ill, were taken in, and a large proportion of the patients in the bell-tents, probably about half, were quite able to look after themselves.

In the distribution of the patients in the tents and marquees, a classification according to the nature of the disease, and as between the wounded and sick, was to a certain extent carried out, but this classification was not perfect. Some bell-tents had six patients in them, and perhaps occasionally more, but not, we think, severe cases. With very few exceptions there would not be more than four enteric fever patients in one bell-tent. For some days the number of trained orderlies was wholly insufficient, and it was probably owing to this that one or perhaps two cases occurred at this hospital of men wandering away during the night. During April, when the largest number of patients treated in the hospital at one time appears to have been about 320, there was a staff of three surgeons and 48 orderlies. Of these orderlies 15 were of the Royal Army Medical Corps, 11 men of bearer companies, 10 of the Cape Bearer Company, and 12 ordinary regimental orderlies. Those of the bearer company, as well as of the Royal Army Medical Corps, were trained men. On the arrival of the second half of the hospital on the 4th May two more doctors were added to the staff. In the bell-tents, owing to the want of change of clothing and the other circumstances to which we have called attention, men brought into the hospital in their khaki had to lie in it without change, and of course could not, and did not, have their bodies properly washed. Mrs. Franklin, an inhabitant of the town, says in her evidence that she offered pyjamas to a field hospital to enable the men to have a change of clothing, but that the offer was refused on the ground that the men in the bell-tents could not, without risk, be stripped of their clothing. But she could not name the particular field hospital to which she referred, and it is therefore not clearly identified with that which we are now dealing with. Dr. Wm. C. Scholtz of the Langman Hospital in his evidence also gives an instance where a proffered gift of pyjamas and other articles was, in the beginning of May, refused by the medical officer of a field hospital (apparently that of the 12th Brigade) on the ground that there was already a sufficiency of the articles in the hospital (*vide* Minutes of Evidence—Questions 5379, 5380). There was a deficiency of bed-pans and night commodes, both in the bell-tents and in the marquees. The effect of this deficiency would undoubtedly be prejudicial to the treatment of severe enteric and dysenteric fever cases and the cause of discomfort to many patients.

There was much conflicting evidence as to the condition of the bell-tents after rain. On the whole, we come to the condition that though

after heavy rain there was some damp in some of the tents, the tents inside could not fairly be called wet, and the men inside could not properly be described as lying in the mud. There were not many days on which it rained in Bloemfontein during the period we are now considering, but when the rain did come the downfall was heavy. However, we do not think the dampness to which we have referred caused any material suffering or annoyance to the patients. A few of them may have been for two or three days in some of the bell-tents without sufficient blankets, but with these exceptions the men had a proper supply of blankets and waterproofs.

This hospital suffered, in common with all others in Bloemfontein, from a deficient supply of fresh milk, but we think the resultant ill effects have been much exaggerated. It is true that a few patients do not like tinned milk, especially if sweetened, but the majority are perfectly satisfied with tinned or preserved milk if it be of good quality, and that supplied to the troops in South Africa generally came within that category. Some of the patients who complained of condensed milk only did so after they were told that it was not fresh milk, not having noticed the difference before. So far as concerns the health of the patients, in a country like South Africa, where fresh milk was so liable to turn sour before it could be got to the patient and to contamination before it reached the hospitals, the patients who had the condensed milk did not suffer in contrast with those who received the fresh. As a matter of fact, the enteric fever patients in No. 9 General Hospital who for some time were fed almost exclusively on the former did as well as those who received the latter. Opinions, however, may differ as to the relative advantages, even in South Africa, of fresh and condensed milk, and no doubt, as a rule, it is advisable that the first-mentioned should be used where it can be obtained of good quality. In the field hospital we are now considering, the bad cases of enteric fever appear, generally speaking, to have obtained a sufficient allowance of it. With regard to medicines, medical and surgical appliances, stimulants, and food, there was, practically speaking, no deficiency.

As appears from the above summary of the condition of things, this hospital was in many respects unsatisfactory, but the results upon the patients were not so bad as might have been anticipated. The deaths up to the 4th May have been ascertained to have amounted to only 4 per cent. of the total number of patients received, and up to that time there were only four deaths in the bell-tents altogether, of which but one resulted from enteric fever, the immediate cause being sudden perforation.

Before passing from this hospital, we should perhaps refer to a suggestion that four men died in consequence of being improperly removed to the Portland Hospital. We have investigated this, and believe it to be unfounded.

Other field hospitals.—**With regard to the other field hospitals their condition was similar to but rather better than that of the 12th Brigade.**

No. 8 General Hospital.—**With regard to this hospital the Commissioners say that in its early days it was in an unsatisfactory condition. Between May 2nd and 3rd nearly 500 patients arrived. The hospital was soon overcrowded and always understaffed, and in the opinion of the Commissioners there was "some want shown of energy and of proper administrative and organising power on the part of the principal officers." Further, friction arose between the civil surgeons and the members of the Royal Army Medical Corps, and even between the senior members of the Royal Army Medical Corps themselves. To the Commission it is a matter for surprise that more vigorous steps were not taken by Surgeon-General Stevenson and by Colonel Exham to put an end to a condition of affairs which could only result in disorganisation. The report proceeds:—**

Referring again to the overcrowding of this hospital, we may point out how great it was, especially in May. Originally the equipment was, as is usual in hospitals of the kind, for 520 beds. It subsequently got some further equipment, but not sufficient for the large number of patients it had to deal with. During the whole of May there was an average of 1200 patients in the hospital, and on one day the number reached was 1398 men and 21 officers. The doctors and orderlies were too few in number to properly cope with such a condition of things, and matters were made worse by their not being properly looked after and supervised. The deficiency of orderlies was increased by sickness amongst them. Doctors and orderlies alike were all overworked and, possibly as a result of this overwork, some of the orderlies appear to have been inattentive, and a few cases of drunkenness occurred amongst them. For some weeks the orderlies were kept working 36 hours out of 48. Again, the supply of nurses for some time was very insufficient. For several days after the hospital started it had only three nurses fit for active duty. Then some more joined, but a few of these were ill, and the numbers were not large; in fact, there were not sufficient nurses until quite the end of May. This scarcity of nurses does not appear to have been the fault of the head medical authorities at Bloemfontein, for Lieutenant-Colonel Beamish, the principal medical officer of this hospital, says in his evidence that he, generally speaking, got all the nurses he asked for (*vide* Minutes of Evidence—Question 8297). A few of the nurses in this hospital were themselves not wholly satisfactory.

There was also a deficiency until the beginning of June of many important things, such as hospital clothing and bed utensils, and there appears to us to have been a want of energy shown in doing anything towards improvising temporary utensils, or taking steps to remedy the defects caused by the absence of proper commodes and bed-pans. The lack of bed utensils, of course, had the usual effect upon the patients' health and comfort, and on account of the deficiency of hospital clothing patients were compelled to lie in their khaki without change, and without being properly and thoroughly washed. We find complaints accordingly with regard to this hospital, which we think in some cases were well-founded, that men were not properly nursed, that typhoid patients, though probably not of a severe type, had in some instances to wash and tend themselves, that night-stools were not properly emptied, and beds not always kept as clean as they might have been. The linen used has been the subject of some complaint, for it appears that in this hospital the washing was not properly done, although at that time the other hospitals in the town succeeded in getting their washing properly attended to. The want of proper management of the hospital was further shown by the delays that occurred in making a thoroughly proper selection of the cases for the purpose of distribution amongst the tents. The charge was also made that for some time the latrines were not properly covered up, and that evil smells resulted therefrom. There was also considerable delay at times in serving the patients with their food. The cook, Corporal H. Sheridan, says that this arose partly on account of the difficulty experienced in getting good water in sufficient quantities, and partly because the hospital was deficient in its supply of cooking utensils and of assistant cooks. In this connexion it should be remembered that the hospital kitchen was of the ordinary camp type and therefore liable to be interfered with by the weather and was originally intended for the supply of only 520 patients. The patients in the marquees did not suffer so much from the state of things above indicated as those in the bell-tents, their main wants being in respect of bed-pans and night commodes. Some complaints were also made as to there being at times a deficiency of blankets in this hospital. Undoubtedly there was a shortage under this head in some of the bell-tents for a few days on the arrival of large convoys; otherwise we do not think the patients suffered from lack of either blankets or waterproofs. As regards the patients in the bell-tents arriving without a proper supply of blankets it is difficult to understand why they were not at once furnished with more blankets. For, though the evidence is somewhat conflicting on the point, we come to the conclusion that there was at all times in this hospital a sufficient store of blankets, and beyond all question there was a sufficient supply in the principal headquarters' stores in Bloemfontein. We think that the fact of there being in the cases we have indicated a deficient supply (though only for a few days) for some of the patients arriving is explained by the want of arrangement in the hospital. Those who noticed the deficiency do not appear to have known to whom to apply to get the blankets that were in store.

As an instance of the lack of organisation we may mention that when deficiencies were noticed some officers seemed not to know to whom to apply. We have also to note that properly qualified officers of this hospital did not attend to meet the large convoys arriving.

Amongst other results we find complaints that some patients, who ought not to have been allowed to do so, had to walk from the place where they arrived in the hospital to the tents into which they were to be received. No doubt Lieutenant-Colonel Beamish, the principal medical officer, owing to the crowded state of his hospital had many things to attend to and great difficulties to meet with, and this probably accounts for the fact that he was so seldom seen in the tents of the hospital or amongst the patients.

On the other hand, we have to state, as complaint was made about it, that in our opinion the site of the hospital was a good one, and further, in favour of this hospital, we must add that considering the circumstances the mortality in it was comparatively small, as will to a certain extent be apparent from the following short list collected from Lieutenant-Colonel Beamish's return (*vide* Appendix—*Beamish*):—

Dates.	Average daily number of patients.	Total number of deaths during the period covered.
23rd April to 30th April, inclusive...	188	5
May	1198	121
June	866	66
July	641	18
August	526	6

From April to the end of August 234 wounded soldiers were treated in this hospital without the loss of a single case.

No. 9 General Hospital.—**The condition of things in this hospital was similar to that existing in No. 8 General Hospital, although with the exception of its first principal medical officer it had upon the whole an excellent staff, the members of which worked well together throughout. Owing to its being near the railway station it was often greatly overcrowded, as it had to be used as a receiving station for cases brought down from the front. Many of the orderlies were untrained and several were rough and inattentive at night. The milk-supply was deficient as in No. 8 and at times there was a scarcity of rugs and blankets. The average daily number of patients was: in May, 1276; in June, 860; in July, 502; and for the first six days of August, 399. The total number of deaths was, from April 19th to the end of September, 279, which the Commissioners consider very small under the circumstances. Concerning the milk the report says:—**

With regard to one statement in particular concerning the milk an erroneous impression about it might be gathered from some of the evidence unless the true facts be stated. One witness spoke about the condensed milk being mixed in baths, as if no care was taken and as if the product was likely to be contaminated or affected. As a matter of fact we have seen these so-called baths. They are tin utensils called ablution tins and quite suitable for the purpose of mixing condensed milk with water and have been kept solely for that purpose, and the milk has been properly and efficiently mixed in them, the water used being good.

Private hospitals.—These were well managed and the Commissioners say but little about them. The Portland Hospital was not flooded nor was the Langman Hospital overcrowded.

Hospitals in the buildings.—With regard to these the Commissioners found but little to complain of. There was at first a deficiency of mattresses and the complaints made as to the Raadzaal Hospital that there was no proper separation of the wounded and those suffering from enteric fever and that convalescents were sent away under circumstances in which they should not have been allowed to depart are considered to have been not established.

CAUSES OF THE DEFECTS IN HOSPITAL ADMINISTRATION ON THE ADVANCE.

Generally speaking, the causes of the defects were mainly two: difficulties of transport and the extent, suddenness, and virulence of the enteric fever epidemic which, however, could not have been foreseen. It was mainly due to the conditions existing at and after Paardeberg. As to delays in bringing up hospitals the report points out that they were got up as soon as they could be. The *personnel* of No. 9 General Hospital was sent up before the equipment and was not idle before the hospital opened as Mr. Burdett-Coutts thought.

Delay in bringing up staff.—On this point the Commissioners say:—

In the beginning of April Surgeon-General Wilson, seeing the condition of things in South Africa, telegraphed to England for four more general hospitals and for more civil surgeons, and on arriving at Bloemfontein on the 23rd April, seeing the position of affairs there then, he sought for and obtained more doctors and nurses in South Africa itself. But these steps came rather late. We think the deficiencies of the staff at Bloemfontein were not thoroughly realised as soon as they might have been and that more doctors might have been obtained and sent up so as to supply these deficiencies earlier. We cannot think that the difficulties of transport, which we are fully aware of, could have prevented doctors being obtained and sent into the town. The lack of sufficient nurses gives rise to similar comments. And with regard to the point that at one time there was no sufficient accommodation for more nurses, it appears to us that though under the circumstances it was right on the part of the authorities not to convert the hotels into hospitals, yet one or more of the hotels might have been employed to afford accommodation for nurses.

As to the deficiency of orderlies, all we can say is that what were really required were properly trained orderlies. These were not forthcoming, and we think the medical authorities did their best in employing as they did such partly trained or untrained men as they could obtain.

Delay in supplying deficient articles.—The Commissioners think that commandeering was not enough resorted to. The deficiency in bed-pans should have been more quickly met by supplies from the base than was the case. Heavy articles were difficult to obtain from the base, but, says the report:

Some witnesses were apparently under the impression that there was no difficulty in sending even heavy articles up by the railway to Bloemfontein. Mr. Burdett-Coutts, M.P., in his evidence illustrates the point by reference to the fact that his own horses were sent up; but at that time horses were being sent up because remounts were urgently needed at the front, and his horses were forwarded because they were consigned as remounts to an officer at the front (*vide* Appendix—*Price* 2).

In conclusion, though we have pointed out in what respects in our opinion there has been some delay or mistake in not providing further supplies of requisites for the hospitals in the town, we think it right, in considering and estimating the difficulties in the way of the principal medical officer in the town, to call attention to the fact that, in addition to the multitudinous affairs with which he had to deal, the medical officers under him did not always bring to his notice the true condition of things in their hospitals.

Delay in removing patients from the railway station.—As to this complaint, which the Commissioners say is in some degree justified, the report proceeds:—

From and after its first occupation the town was used as a base to which were consigned the sick and wounded from the front, especially after Lord Roberts's advance to Kroonstad commenced. These patients were generally brought into the town by railway and on reaching the railway station, unless they were consigned to No. 9 General Hospital after its siding was made, they had to be taken from the station by ambulances to the various hospitals into which they were to be received. For some time the number of ambulances available for the purpose was very small and it was a matter of difficulty always to have a supply at the station immediately on the arrival of the train. The duty of the medical officers at the stations on the line from which the sick and wounded were sent was to notify by telegraph to the principal medical officer at Bloemfontein the dispatch of the train and the probable hour of its arrival. But owing to the condition of the line, and the interruptions due to the pressure of the traffic and the acts of the enemy, the trains very often arrived at the station hours after the time fixed or at which they were expected. The ambulances being few and much in request could not be kept permanently at the station and so on several occasions some two to four hours elapsed between the arrival of the trains and the removal of the patients to the various hospitals. Moreover, the telegraph line was often cut or out of working order and even when in proper condition was often blocked by urgent military messages, and it is said that sometimes the medical officers sending patients by train forgot to telegraph in time to the principal medical officer at Bloemfontein. In those cases (which, however, we think were few) the sick and wounded would arrive without the authorities at Bloemfontein being made aware of the fact and still greater delay might arise before they could be removed to the hospital. In these various ways the patients were sometimes delayed at the station and in some few cases had to remain for some time without being attended to by a doctor or obtaining any refreshment or medical comforts, such as milk, beef tea, or stimulants. Indeed, on occasions, owing to the train having occupied a longer time on its journey than had been anticipated, and for which it had been supplied, the men may have been without refreshment for some time, and suffering must necessarily have been thereby caused, especially to such of the patients as could not look after themselves. These occurrences were prevented after a time by the establishment by Colonel Exham of a telephone from the railway-station to the principal medical officer's quarters in the town, and also by a medical officer being always kept at the station with medical comforts ready. Moreover, as time went on more ambulances became available for the removal of the patients. But the attendance of a medical officer at the station was not arranged for until the end of May. It is said that before that time the staff of doctors in Bloemfontein was so small in comparison with the work to be done that a medical officer could not be spared for the purpose. We think, however, there is good cause for complaint in the fact that steps were not taken earlier to remedy the evils we have referred to, although after Colonel Exham's arrival at Bloemfontein we are satisfied he was constantly at the railway-station, and that he discharged his duties very zealously.

One incident of the kind has been the subject of much evidence, and was particularly referred to by Mr. Murray Guthrie, M.P., and Mr. Burdett-Coutts, M.P., the latter of whom, however, only spoke from information given to him by others. As it has been considerably commented upon, we inquired into the details. The facts, which apparently were not fully known to Mr. Murray Guthrie, are not so bad in several particulars as they were in the first instance represented. We think it right to state them fully. The train, which contained 179 patients in all, consisted of several trucks, which were at the time the only means of transit available. It left Zand river on the 22nd May, at noon, and arrived at Bloemfontein at 6 A.M. on the 23rd. One of the trucks contained eight patients suffering from fever, which subsequently proved to be enteric. This truck was next to the engine, and immediately behind it came some empties, and then followed the trucks containing all the other sick and wounded men. As the train was expected to obtain refreshment at Smaldeel, only a little was served out at Zand river, that duty being committed to a soldier who was sufficiently well to be able to undertake it. At Smaldeel, owing to the hour of arrival and the disorganisation incidental to the then condition of the campaign in that neighbourhood, the men appear to have received no further comforts, but a little later, before reaching Bloemfontein, two nursing sisters came on board the train and gave the men some milk, brandy, and extract of beef. Arrangements had been made at Bloemfontein for the reception of this train, which was to be drawn up on the line opposite No. 9 General Hospital, in order that the patients might be easily conveyed there. But when it reached Bloemfontein, by a mistake of the railway shunters, who did not notice that the truck with the eight men in it was between the empties and the engine, and who thought that all the patients were contained in the trucks at the other end, two empties with the trucks in question attached were shunted on a siding, as forming no part of the train from which the patients were to be removed. The consequence was that when, in due course, the 171 patients were taken opposite No. 9 General Hospital and detrained, the truck with the eight men in it remained for some time unnoticed on the siding. The authorities at No. 9 were of course unaware of the fact. The railway staff officer noticed the men, but was under the impression that the authorities of No. 9 General Hospital knew that they were there and would send for them shortly. Consequently, he did not inform Colonel Exham of the circumstance as quickly as he should have done. Finding, however, that they were not sent for, he at last communicated with Colonel Exham, who thereupon at once went to the station and saw the men. This was about 11.30 A.M. In the meantime, about 9 or 9.30 A.M., Mr. Murray Guthrie had noticed the men and spoken about them to the railway staff officer. Assistance was obtained by them and the eight men were removed from the wagon and put on the platform under shelter, with their blankets and great coats. A little later Mr. Murray Guthrie kindly obtained some bovril and milk from his store, and had it given to the men. On his arrival at 11.30 Colonel Exham was informed of the patients having been attended to in the manner stated, but after visiting them again half an hour later, he at once went to No. 9 General Hospital and arranged to have warm milk and beef-tea provided, which was promptly done. As all the ambulances at his disposal were that morning engaged he obtained a spare ambulance from the Irish Hospital and sent it to the station. The eight patients were then removed to the Irish Hospital, the last one arriving about 2 P.M. or a little later. They were neither in a state of collapse nor dying, as one of the witnesses seemed to fear. When Colonel Exham saw them at 11.30 he found them mostly asleep, and he says that none were in such a condition as to make an early removal an urgency. This is not in accordance with the testimony of some other witnesses, but it seems to be corroborated by the facts which have been ascertained. The men have been traced, and it appears that none of them died at the Irish Hospital, although the contrary has been alleged. Four were transferred from the Irish Hospital to the base and the remaining four were transferred to No. 9 General Hospital. Only one out of the eight died. He became convalescent from the attack of typhoid fever, but about the first week in July, during the wet weather, contracted pneumonia, from which he died on July 13th. The facts of the case speak for themselves.

Care of Convalescents and Others sent from Bloemfontein.

As regards sending down patients to the base the Commissioners consider that the authorities did their best under existing conditions. It was very desirable that the pressure should be relieved by sending down such as were able to bear the journey, and on the whole the selection of cases was wisely made, though here and there mistakes were made.

One deficiency should be noticed. For a time some trains had a deficiency of buckets sent with them by the authorities at Bloemfontein. This deficiency caused much discomfort, and the oversight is to be regretted as it was easily remediable, and as a matter of fact was set right on attention being called to the matter by Dr. Conan Doyle.

Sanitation in the Town.

This was not wholly satisfactory, but the great outbreak of typhoid fever was not due to preventable causes.

Some Special Complaints.

There were some special allegations made by certain witnesses which we ought to refer to before we leave the subject of Bloemfontein. It is said that on one occasion 20 typhoid patients were improperly removed to the Portland Hospital. We have inquired into this allegation and as a result we have to state that in our own opinion the removal was necessary in the interests of the patients.

A gruesome story of a corpse being stuffed into a lavatory was mentioned by Mr. Burdett-Coutts, M.P., but he states that he only spoke of the matter from information given to him. Inquiry has been made in all quarters to find out whether there is any foundation for this allegation. No such case can be found to have occurred either at Bloemfontein or elsewhere in South Africa, and we are satisfied that Mr. Burdett-Coutts was misled by his informant.

Some observations have also been made with reference to the dead at Bloemfontein, as if the corpses, owing to their great number, were dealt with in a hurried or neglectful way. This is not the fact. In the first place the numbers of men dying in Bloemfontein have been overstated by some witnesses. There were not 50 deaths a day; the maximum was 40, and that only for one day. Each body was buried separately and with every respect and care, and each grave was numbered and the number and name of the dead man registered.

As to Certain General Charges.

As regards certain general charges, we think it only right to say that a false impression is conveyed of the state of things existing at Bloemfontein by such statements as those to the effect that in particular hospitals there were thousands of men in deadly disease, or that thousands of men were left unnursed, or that men were dying against convalescents in the tents (though no doubt in a few cases men may have died next convalescents), or other like general statements. The substantial grounds of complaint at Bloemfontein we have sufficiently pointed out above, and there is nothing in them to justify any charge of inhumanity or of gross or wilful neglect, or of disregard for the sufferings of the sick and wounded on the part of the medical authorities or others having the duty of looking after them.

Lastly, we should add that some few particular complaints and statements affecting Bloemfontein have been made which have not been particularly dealt with by us. With regard to these, we need only say that our silence is to be taken as indicating that, in our opinion, those complaints and statements are not well founded.

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6718 births and 4804 deaths were registered during the week ending Feb. 23rd. The annual rate of mortality in these towns, which had been 19·7 and 19·5 per 1000 in the two preceding weeks, rose again last week to 21·2. In London the death-rate was 20·8 per 1000, while it averaged 21·6 in the 32 provincial towns. The lowest death-rates in these towns were 11·7 in Burnley, 13·3 in Huddersfield, 13·6 in West Ham, and 14·7 in Croydon; the highest rates were 25·4 in Salford, 25·5 in Birmingham, 26·2 in Manchester, 27·3 in Liverpool, and 36·7 in Plymouth. The 4804 deaths in these towns included 387 which were referred to the principal zymotic diseases, against 397 and 348 in the two preceding weeks; of these 126 resulted from whooping-cough, 94 from measles, 17 from diphtheria, 33 from diarrhœal diseases, 31 from "fever" (principally enteric), and 26 from scarlet fever. No death from any of these diseases occurred in Wolverhampton, in Norwich, in Halifax, or in Gateshead; in the other towns they caused the lowest death-rates in Croydon, Oldham, and Huddersfield, and the highest rates in Bristol, Liverpool, Blackburn, and Preston. The greatest proportional mortality from measles occurred in Liverpool, Bolton, and Hull; from whooping-cough in Bristol, Cardiff, Nottingham, and Preston; and from "fever" in Derby. The 77 deaths from diphtheria included 27 in London, nine in Leeds, six in Leicester, four in West Ham, and four in Salford. No fatal case of small-pox was registered last week in any of the 33 towns, and only one small-pox patient remained under treatment in the Metropolitan Asylums hospitals on Saturday last, Feb. 23rd. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1834, against numbers decreasing from 2535 to 1876 on the eight preceding Saturdays; 162 new cases were admitted during the week, against 178, 145, and 142 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 323, 397, and 420 in the three preceding weeks, had further risen to 493 last week, but were 60 below the corrected average. Influenza was certified as the primary cause of 32 deaths in London last week, as compared with 15, 12, and 16 in the three preceding weeks. The causes of 59, or 1·2 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Salford, Oldham, Bradford, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Sheffield, and Newcastle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·2 and 22·6 per 1000 in the two preceding weeks, rose again to 23·7 during the week ending Feb. 23rd, and exceeded by 2·5 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·0 in Leith and 18·5 in Perth to 23·0 in Edinburgh and 27·0 in Glasgow. The 742 deaths in these towns included 36 which were referred to whooping-cough, 19 to measles, 16 to diarrhœa, 15 to small-pox, six to "fever," four to diphtheria, and three to scarlet fever. In all, 99 deaths resulted from these principal zymotic diseases, against 103 and 106 in the two preceding weeks. These 99 deaths were equal to an annual rate of 3·2 per 1000, which was 1·5 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 43, 37, and 33 in the three preceding weeks, rose again last week to 36, of which 25 occurred in Glasgow, five in Dundee, and three in Edinburgh. The deaths from measles, which had been 14 and 25 in the two preceding weeks, declined again to 19 last week, and included 10 in Edinburgh, four in Glasgow, two in Dundee, and two in Aberdeen. The fatal cases of diarrhœa, which had been 27, 18, and eight in the three preceding weeks, rose again last week to 16, of which five were registered in Glasgow, two in Edinburgh, two in Dundee, two in Aberdeen, and two in Greenock. The deaths referred to small-pox, which had been 24, 11, and 20 in the three preceding weeks, declined again to 15 last week, and included 13 in Glasgow, one in Aberdeen, and one in Paisley. The fatal cases of "fever," which had been 10 and four in the two preceding weeks, rose again last week to six, of which two were recorded in Glasgow, two in Edinburgh, and two in Dundee. The four deaths from diphtheria showed a marked decline from the numbers in recent weeks, and included two in Glasgow, where two of the three deaths from scarlet fever were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 158 and 153 in the two preceding weeks, rose again last week to 177, but were 185 below the number in the corresponding period of last year. The causes of 38, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·4, 34·0, and 34·3 per 1000 in the three preceding weeks, declined again to 33·7 during the week ending Feb. 23rd. During the past four weeks the death-rate in the city has averaged 32·4 per 1000, the rates during the same period being 18·7 in London and 21·1 in Edinburgh. The 224 deaths belonging to Dublin registered during the week under notice showed a decline of four from the number in the preceding week and included 11 which were referred to the principal zymotic diseases, against 18, 16, and 10 in the three preceding weeks; of these, four resulted from "fever," four from diarrhœa, and three from whooping-cough. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·5 in London and 3·2 in Edinburgh. The deaths referred to different forms of "fever," which had been three, five, and two in the three preceding weeks, rose again to four last week. The fatal cases of diarrhœa, which had been two in each of the three preceding weeks, increased last week to four. The deaths from whooping-cough, which had been 12, nine, and three in the three preceding weeks, were again three

during the week under notice. The 224 deaths in Dublin last week included 35 of children under one year of age, and 79 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight increase over the number in the preceding week. Three inquest cases and six deaths from violence were registered; and 73, or nearly a third, of the deaths occurred in public institutions. The causes of 19, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE under-mentioned surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Lawrence Bidwell, Edward Henry McSherry, Walter James Bearblock, William Hackett, Charles Geskie Matthew, Thomas Austen, and Joseph Chambers.

The following appointments are notified:—Staff Surgeon W. J. Bearblock to the *Archer*. Surgeons: O. Rees to the *Gibraltar*, R. F. Clark to Plymouth Hospital, and B. Ley to Royal Marine Depôt, Deal. Civil Practitioner: A. J. Sharpe to be Surgeon and Agent at Whitby.

ROYAL ARMY MEDICAL CORPS.

Major S. O. Stuart holds himself in readiness to embark for South Africa at an early date.

The undermentioned surgeons-on-probation to be Lieutenants: Albert John Walton Wells, George Faber Sheehan, Henry Harold Scott, Henry Arthur Bransbury, Mervyn Winfred Falkner, Richard Nason Woodley, Eugene Ryan, Edward Ernest Parkes, James Valentine Roche, Alfred John Hull, Reginald Vionnée Cowey, James Conway, John Humphrey Barbour, Frederick England Robinson, Samuel Mason, John Southey Bostock, and Arthur Henry McNeil Mitchell.

INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the appointment of the undermentioned surgeons-on-probation to the Indian Medical Service:—To be Lieutenants: Charles William Melville, Robert McCarrison, James Masson, Norman Septimus Wells, William Maurice Anderson, Edmund Hamilton Blake Stanley, William Hugh Leonard, William Douglas Pringle, Andrew Watson Cook Young, James Graham Goodenough Swan, Robert McLauchlan Dalziel, James Jackson Robb, Abdur Shaik Ruzzak, and Robert Basil Boothby Foster.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Thomas F. Devane, 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment), to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Banff: Supernumerary Surgeon-Captain F. W. Grant to be Surgeon-Captain on the Establishment. *Rifle:* The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): The undermentioned gentlemen to be Surgeon-Lieutenants:—Alexander Aitken Ross and James Scott. 1st Hertfordshire Volunteer Battalion the Bedfordshire Regiment; Surgeon-Captain R. Odell resigns his commission. 2nd Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Lieutenant-Colonel B. Goff resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement.

THE COST OF MAINTENANCE AND TREATMENT IN MILITARY HOSPITALS IN THE LEVANT.

Dr. Barthélemy of the French navy, in the course of an interesting article in the *Archives de Médecine Navale* for November last on the sanitary condition of a battalion of marine infantry recently quartered in Crete, gives an account of a notable experiment which was carried out under his orders with a view of determining the cost of maintenance and treatment in improvised hospitals for troops at outposts or in camps remote from headquarters. Owing to the isolation of Halepa, where the battalion was encamped, it was decided that all hospital supplies were to be procured locally under the supervision of the regimental medical officer, and in order that the expenditure might be conclusively established Dr. Barthélemy took steps to find out the value of the medicaments and other necessaries which were obtained from France. The rent of the building where the improvised infirmary was installed, amounting to 140 francs per mensem, was also included in the accounts, as well as every other item that could legitimately be imputed against the upkeep of the establishment. Throughout the whole of 1898, says Dr. Barthélemy, we devoted ourselves to this work after a very conscientious fashion, with the following result. After all expenses were paid it was found that each patient cost the State the sum of 2¼ francs per diem. It is a very low charge, he continues, by comparison with the sums exacted from military and naval patients in the civilian hospitals of these regions. At Smyrna, for example, every individual admitted is made to pay 12 francs per diem. The simple facts here related demonstrate with great clearness the expediency of organising self-contained infirmaries for troops, wherever they may be stationed, whether it be in the colonies or in foreign countries. These sanitary institutions can be installed everywhere under regimental auspices alone. The administration they demand is extremely simple, while the *personnel* required is less numerous and also less expensive than is the case in hospitals properly so-called. The surgeon-major of the regiment or of the battalion can himself supervise and control the arrangements. He can send his sick in at the most opportune moment, can follow their fortunes during the course of their diseases, and is able to apply the treatment most suitable to each man's case and constitution, for he knows them all well. When these infirmaries are well installed, which can always be the case, the patients are just as well off with regard to hygiene and comfort as they would be in a civil or colonial hospital, and this notwithstanding the important circumstance that the cost of their upkeep in the latter would be at least three times as great.

MILITARY EFFICIENCY IN WAR.

The debate in the House of Commons on Mr. Lambert's proposed amendment to the address *à propos* of the number of surrenders of British troops and the loss of guns during the present war had the effect of drawing an explicit declaration from Mr. Brodrick on the part of the Government. Mr. Brodrick promised that the whole subject would be promptly and firmly dealt with, in order to ascertain all the information possible in regard to the many "regrettable occurrences" that had taken place during the campaign in South Africa. It seems that in future the practice in the army will be more assimilated, and rightly so, to that of the navy in the case of loss of or accident to one of His Majesty's ships. In addition to the dispensation of punishments that has already taken place in connexion with the present war the Government will bring to trial by court-martial all those who were *primâ facie* responsible for surrenders. Where, for want of a *primâ facie* case, it is impossible to deal with specific individuals, the cases will be made the subject of general investigation at the end of the war. It is quite possible that in some instances where troops had had little or no previous military training it was no lack of courage but an absence of corporate discipline and experience on their part that led to their surrender.

HONORARY PHYSICIANS AND SURGEONS TO THE KING.

The following appointments have been made:—Honorary Physicians to the King: Dugald McEwan, M.D. Glasg., Inspector-General (retired); Sir James J. L. Donnet, K.C.B., M.D. St. And., Inspector-General of Hospitals and Fleets; Sir John Watt Reid, K.C.B., M.D. Aberd., LL.D., Director-General of the Medical Department of the Navy (retired); Adam B. Messer, M.D. Edin., Inspector-General of Hospitals and Fleets (retired); and Henry C. Woods, M.V.O., M.D. St. And., Inspector-General of Hospitals and Fleets (extra). Honorary Surgeons to the King: Sir James Jenkins, K.C.B, M.D. Glasg., Inspector-General of Hospitals and Fleets; Timotheus J. Haran, Inspector-General of Hospitals and Fleets; Sir James N. Dick, K.C.B., Director-General of the Medical Department of the Navy (retired); William H. Lloyd, M.D. St. And., Inspector-General of Hospitals and Fleets; Alfred G. Delmege, M.V.O., M.D. R.U.I., Deputy Inspector-General of Hospitals and Fleets (extra).

THE WAR IN SOUTH AFRICA.

There has been great activity recently in the prosecution of the war, and the news is of a much more satisfactory and

encouraging nature. According to an official return recently issued the total effective strength of the British forces serving in South Africa at the present time amounts to 204,949 men. Upwards of 20 cases of plague have occurred at Cape Town since the outbreak of that disease was first notified. The cases have been mainly among the native population, but several Europeans have also been attacked. The disease does not appear to have spread rapidly or to have been of a very virulent type, for the mortality has not so far been great; the worst feature perhaps about it is that the cases have not been confined to one or two, but have occurred in several, districts of the town. Very active measures have been adopted by the local authorities with the view of limiting the spread of the infection. As regards the British forces in the field enteric fever continues to occupy by far the first place in the casualty returns.

SOUTH AFRICAN NOTES.

Lieutenant W. M. Power, R.A.M.C., Lieutenant E. B. Knox, R.A.M.C., Captain N. Faichnie, R.A.M.C., and Civil Surgeons A. Young and S. H. White have returned to England from South Africa.

Captain F. S. Brereton, R.A.M.C. (invalided), and Civil Surgeon M. W. Renton are returning home in the *Simla*.

Lieutenant Forbes Winslow, R.A.M.C., and Civil Surgeon Mowatt are reported improving (Pretoria, Feb. 20th).

Major J. S. Edye, R.A.M.C., Lieutenant J. M. Buist, R.A.M.C., and Civil Surgeons W. J. Moir and E. L. Mansel Renton have been discharged from hospital to duty.

The military hospital at Stoke has proved of great value during the South African War. Military invalids from the seat of war were first received there on May 8th last. Some 2200 have been received for treatment. On Feb. 18th 76 invalids remained in the hospital, but a fresh party of 150 arrived on Feb. 23rd.

THE NEW PERMANENT UNDER-SECRETARY AT THE WAR OFFICE.

Mr. Brodrick is to be highly congratulated on the appointment of Colonel E. W. D. Ward as the successor to Sir Ralph H. Knox. Colonel Ward is a thoroughly capable man and has had ample opportunities for showing his quality in peace and war, and the appointment of "the best commissariat officer since Moses," as Sir George White was justified in speaking of him after the siege of Ladysmith, will commend itself to all. Colonel Ward is a capital organiser and, like men who really know their work, he has foresight, self-reliance, and no fussiness. His appointment is an earnest of the sincerity of the War Minister's expressed intentions as to army reform.

LUMSDEN'S HORSE IN CALCUTTA.

On the return of Lumsden's Horse to India from their war service in South Africa they met with an enthusiastic reception. The Viceroy, in the course of a speech at Calcutta welcoming the corps, congratulated Colonel Lumsden and his officers and men on their record in South Africa. Lord Curzon dwelt on the fact that besides the loss of their gallant second in command, Major Showers, only five others were killed, while two only died from disease in the entire campaign. The total casualties were less than 24, which in a force of over 250 men was, Lord Curzon considered, a remarkable result.

DENTAL SURGEONS FOR THE SERVICES.

In a paper read by Mr. Browne-Mason of Exeter at a recent meeting of the Western Branch of the British Dental Association, the author urged the appointment of dental surgeons in connexion with the army and navy. In June, 1900, Mr. Browne-Mason examined 151 soldiers invalided from South Africa at the Station Hospital, Devonport, and found that only four had sound sets of teeth. The author holds that early attention to the teeth would be of great benefit to the army and navy, more especially the latter on account of the earlier age of joining the service.

SOME STATISTICS OF WAR CASUALTIES.

Apropos of the losses in the present war in South Africa it may be interesting to refer to the casualties in some other wars. Dr. Ryerson of the Canadian Medical Staff, in his address at a meeting of the Toronto Clinical Society last year, stated that of the British Army in the Crimea 4602 were killed, while 17,580 died from disease; in the American Civil War, on the Union side, 93,969 were killed and 186,216 died from disease; in the Spanish-American war 454 were killed and 5277 died from disease.

THE OGADEN SOMALIS EXPEDITION.

A telegram from Mombasa, dated Feb. 26th, states that the expedition which was sent to punish the murderers of Mr. Jenner was attacked on Feb. 19th. Among the killed was Lieutenant-Colonel Maitland, I.M.S. (Bombay), and among the wounded Dr. Mann.

MENTIONED IN DESPATCHES.

In a despatch from Sir Redvers Buller, dated Camp Springfield, Feb. 8th, 1900 (omitted from the despatches published in the *London Gazette* of Feb. 8th, 1901), Lieutenant J. J. W. Prescott, R.A.M.C., is "specially mentioned for his care of the wounded in despite of a heavy fire."

ARMY MEDICAL SCHOOL, NETLEY.

The summer session of the Army Medical School commences to-day, Friday, March 1st. The session is to be attended by 35 surgeons-on-probation who have entered the school by competitive examination—28 for the Indian Medical Service and seven for the Royal Army Medical Corps.

Correspondence.

"Audi alteram partem."

"THE DUMMY CORPSE" CASE.

To the Editors of THE LANCET.

SIRS,—As it may be of some interest to the profession I have pleasure in placing before you the story of this extraordinary case.

William Charles Browning, 35 years of age, called upon me on Jan. 14th of this year complaining of difficulty in micturition. I prescribed for him but did not see him again until the 25th, when he once more visited me. On the 29th I was summoned to his room at 253, Vauxhall Bridge-road, S.W., where I found him in bed in a very weak condition with a temperature of 103° F. He complained of severe pains in the loins and constant headache and said that his feet and legs swelled when he was out of bed and that for some time he had been passing very frequent but very small quantities of urine which had been porter-coloured but was then clear, although the smallness of quantity and frequency of micturition still continued. He remained in bed for the following eight days, during which I visited him regularly, receiving samples of his urine each day. It was acid, specific gravity 1025, and always contained considerable quantities of albumin. On one occasion I obtained the reaction for blood, and on microscopic examination there were numerous hyaline and some granular tube casts. Uric acid crystals were present in very large amount. I treated the case in the usual way as one of acute nephritis. On Feb. 4th the albumin had largely increased in quantity, and I went to see Browning earlier than usual and found him very collapsed, deadly pale, almost pulseless, and suffering from a severe rigor. He explained to me that a fire had occurred in the adjoining room during the previous night, that he had jumped out of bed, and almost naked had assisted in extinguishing it. He then said that he should send for his brother, and gave his landlady the letter, which she posted. On the following day (Feb. 5th) Browning appeared to be very drowsy and there were convulsive movements of the limbs. Fearing uræmia I at once took measures accordingly and saw him again at night, at 10 o'clock. Though free perspiration had been induced the drowsiness continued and it was with difficulty that any reply could be obtained to questions.

Next morning (Feb. 6th) at 10 o'clock a man called upon me and I was struck by his general resemblance to my patient, but this was speedily explained by his stating that he was the brother of Browning, who, he informed me, died at four o'clock that morning. He said that he had arrived shortly after my departure the previous night and had found his brother sleeping heavily, but that he awoke at midnight, just recognised him, and then relapsed into deep sleep. "At four o'clock my brother had a fit in which he died." Upon my inquiring into the nature of the "fit"

he gave me the symptoms of uræmic convulsions and I remarked that I could not express surprise considering the grave condition of the patient. In reply to my questions the "brother" explained that he was the only living relative of the "deceased," who had lost his wife two years previously through accidentally taking poison. He wished the "body" to be removed from Vauxhall Bridge-road lest it should be an inconvenience in the house, and I suggested that a respectable undertaker would take charge of it. He paid my account, saying that he wished to take the receipt to his brother's solicitors. I filled in the certificate of the cause of death in the usual way. He supplied me with the necessary details. Owing to his description of the "fit" in which death had been said to occur I certified to uræmia consequent upon acute nephritis. A little later the landlady called upon me and explained that she had admitted the "brother" the previous night and had expressed surprise to him the next morning that he had not summoned her or sent for the medical man when Browning died, but had been told that it was of no use, as death had supervened almost immediately. She was concerned because the "body" was locked up and no one had been to "lay it out." I told her that although neither required by law nor the custom of the profession I should carry out my usual habit of inspecting the corpse, and that she need not worry further.

Some two hours later I called, and the "brother" being still absent I asked if a key could not be found for the folding-doors which separated Browning's room from that wherein the fire had occurred. I said that I did not wish to have to pay a second visit, and that if any difficulties were made as to the room being entered in the "brother's" absence I would be responsible, as he could have no objections to my seeing the body of my patient. On opening the door a seal was broken and this first aroused my suspicions that there was something wrong; but on looking at the bed there was dimly to be seen in the darkened chamber the outlines of a human body covered by a coverlet. Upon removing the latter I found the corpse to be a "make up." Fearing foul play to my patient I at once searched the room, but finding nothing to corroborate my suspicion I locked the door and immediately went to Gerald-road police-station and reported the facts. Thence I proceeded to the registrar's office, and ascertaining that the certificate had not been registered, I left instructions that if anyone presented it the police should be communicated with at once.

Later in the day, accompanied by Detective-Sergeant Bedford of the B Division, I went to the house, and a search revealed that Browning was a senior medical student and that he held a policy in the Pearl Insurance Company for £200. Whilst we were in the house the so-called "brother" arrived, and being confronted with the detective and myself confessed that he was at once the patient, the corpse, and the brother, and that he had done all this to make his relatives believe him dead, as he had just come out of prison. He said that he had no intention of making an improper use of the certificate, and handed it back to me. Questioned as to his illness he replied: "I have been ill, very ill, and am still ill, but I made the most of my symptoms, and I added albumin to the samples of urine sent to you for examination. My temperature was genuine" He further stated that after my last visit on the night of the 5th he had got out of bed and shaved off his moustache, and that disguised he had slipped out of the house and re-appeared as the "brother." Like myself the landlady did not recognise him either that night or on seeing him the next morning, so clever was the change in his appearance. The evidence before Mr. Sheil at Westminster Police-court and the subsequent trial before Mr. McConnell, K.C., at the Clerkenwell Sessions, whereat Browning was charged with making a false statement and obtaining a certificate of death by false pretences, ended in a sentence of nine months' imprisonment.

In conclusion, Sirs, may I be allowed to draw a moral from this strange case? That moral is, the desirability of legislation whereby it shall be made necessary that after death from natural causes in a case that has been attended by a duly qualified medical man the dead body shall be seen by a registered practitioner before the certificate is given, and that such practitioner shall certify, not merely as at present the *cause* of death, but also the *fact* thereof. The State should be responsible to the medical man for this visit and for giving the certificate. If I understand rightly, the desirability of such a change in the law was pointed out to a Government Commission some years ago but nothing was done in the matter.—I am, Sirs, yours faithfully,

GIDEON W. B. MARSH,
L.S.A., B.A. Lond., F.R.Hist.S.

Tachbrook-street, S.W., Feb. 25th, 1901.

MEDICAL MEN AND LIFE INSURANCE PROPOSALS.

To the Editors of THE LANCET.

SIRS,—Doubtless in common with all other practitioners, I am constantly receiving letters from life insurance offices asking for information concerning friends or patients wishing to have their lives insured. The questions often look simple enough, but probably include one which to a medical man who has known his friend or patient for a few years, and his family for more, is not so simple as it looks—"Is there anything else in the history of the patient or his family which the office ought to know?" The actuary is kind enough to add that any reply to such a communication will be regarded as confidential; in other words, that you may give away your friend's or your patient's chances of insurance at ordinary rates without the risk of his knowing that you have done it. There is something in this assurance which shows that the offices are conscious that they are acting, to say the least, questionably. I have long absolutely objected on principle to give such information to offices. They have their own experts to investigate the medical facts of cases and are quite capable of getting all the information necessary for their own protection from the applicant or his lay friends without putting his medical friend or adviser into the false position of serving two masters. The offices have only one excuse—that the proposer often quite innocently gives them a reference to his medical friend or medical adviser, and as far as I know the medical profession has not, as a whole, or through any of its principal authorities, objected to this use of medical men.

I write in the hope that a little ventilation of this point will show the unreasonableness of the practice and lead to its discontinuance by the offices. No fee which they could pay would alter the ethical aspect of the case—except for the worse. I am, Sirs, yours faithfully,

Highbury-place, Feb. 26th, 1901. J. G. GLOVER.

PERFORATION OF THE BOWEL IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—Professor Osler's plea for the prompt surgical treatment of perforation of the bowel in typhoid fever and your leading article thereon, both of which were published in THE LANCET of Feb. 9th (p. 386 and p. 413), should appeal with great force to all members of the medical profession. It is not too much to say that the entire profession is under deep obligation to Professor Osler for speaking his mind so emphatically on this subject through your widely-read columns, and also to you, Sirs, for your earnest endorsement of his important recommendations. It surely now behoves every medical man in attendance on a typhoid fever patient at once to take steps which will enable him, should the necessity arise, to give his patient the benefit of prompt surgical treatment, and a heavy responsibility will attach itself to the individual who fails to follow Professor Osler's advice.

There is one point in Professor Osler's paper to which I should like to draw attention, and this is the remark that perforation of the bowel as a complication of typhoid fever is liable to occur in severe examples of the disease, or in cases associated with delirium, diarrhœa, hæmorrhage, or other abdominal symptoms. Having once lost a patient from a perforating typhoid ulcer who was the subject of the so-called ambulatory form of the disease and who, until the rupture occurred, which took place whilst at stool, was going about his daily work, I am in a position to bear testimony to the oft-repeated statement that this disease, in apparently its mildest form, may terminate fatally from perforation. Bristowe in his work on Medicine points out that perforation not infrequently occurs in patients who have never taken to their beds, and Taylor asserts that in some cases the illness is so slight that patients go about their ordinary occupations until, perhaps,

the use of aperients leads to a fatal perforation, while Professor Osler himself states that in rare instances typhoid fever is unsuspected until perforation occurs. I need not, perhaps, quote any other authorities in support of this well-known insidiousness of typhoid fever. My object in mentioning it at all is to urge upon those concerned the circumstance that skilled surgical aid should be made available *in every case* of typhoid fever, and not only in cases which, from their clinical symptoms, are deemed to be of a serious nature.

Professor Osler divides cases of perforation into three groups. The first group comprises cases which, setting aside the exploratory laparotomy, are found to be inoperable; the second embraces all cases successfully operated on which end fatally from the disease itself; and the third consists of those cases which recover from the disease after successful operation. It seems probable that in the hands of skilful surgeons recovery would be the rule in all cases in which the symptoms, apart from the perforation, were slight in degree.

Attention is drawn in Professor Osler's communication to the difficulty occasionally experienced in the diagnosis of perforation of the bowel, and in this relationship I would point out the advisability of an examination of the chest in all doubtful cases. On one occasion, now some years ago, I omitted to take this precaution and believing my patient was suffering from peritonitis treated him with hypodermic injections of morphia every four hours combined with rectal alimentation. On the third day of this treatment the patient hawked up a pellet of blood-stained mucus, and it was then discovered that he had pneumonia of the base of the right lung, of which disease, apart from acute and sudden abdominal pain with quickened respirations, he had previously shown absolutely no symptoms.

I am, Sirs, yours faithfully,

OSWALD BAKER, M.D. DURH.

Welbeck-street, W., Feb. 17th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 23rd, p. 578, Mr. Aspinall Marsden asks whether some effort cannot be made to establish in our profession a common doctrine on the temperance question. I fear that he cannot have studied your columns very carefully during the past few years and cannot be acquainted with recent literature on this subject. Perhaps, also, he is unaware of the work which has been undertaken by the Society for the Study and Cure of Inebriety. It seems necessary to inform your correspondent that a great effort *is* being made to establish a common doctrine on scientific grounds, but scarcely on the lines suggested by him.

I take leave to object to his suggestion that the modern view regards alcoholism as "a defect of will in relation to intoxicants," and that "the predisposing cause of alcoholism is nervous instability of all kinds." The defective will-power which is supposed to make a man unable to resist the craving for alcohol must be part only of a generally weak will. Does your correspondent deny that the Italians are more sober than the Scots? If he does not will he kindly give us his proof that the Italian is the stronger-minded race of the two? Or, to bring the subject nearer home, does he mean to assert that his teetotal friends tell him that they conquer the desire to imbibe by exerting will-power? Is the explanation not simpler—the teetotaler does not drink because he has no desire? To receive an answer to the question, "Why has the teetotaler no desire?" I refer your correspondent to Dr. Archdall Reid's writings. Then what is this "nervous instability"? What are the causation, pathology, and symptoms of it, if it be a disease? Or is it merely a revived "astral body" or "elementary spirit" of the mystics, or some curious re-christened survival from the iatro-chemical or the vital-fluid school? Or can it be part of some magic diffused from some great man in the profession? It would be well if Mr. Marsden would bring us to closer quarters with this "nervous instability."

The statement that "the children of parents with physical weakness take to narcotics like ducks to water" is far-reaching and awe-inspiring. Does Mr. Marsden mean seriously that parental drinking causes filial drunkenness—that the acquired effects of alcoholism are transmissible? Has he the proof long sought by the scientific world in his keeping? If so, Sirs, may your columns soon be thrown open once more to the exposition of a great discovery.

Your other correspondent "M.D., B.Sc. (Lond.)" is of the serious opinion that some publicans are genuine temperance reformers. Perhaps this is more true than either he or his publican patients imagine. But what are their principles? Do they distribute temperance tracts across the bar? or have they only been reading (and have misunderstood) Dr. Reid's "Present Evolution of Man"? May I tell "M.D., B.Sc.," that I know a wealthy brewer's wife who is a strong and conscientious and active temperance reformer? She collects and preaches to wayward men by the hundred; but the only noticeable effect is that her husband's tied houses are deserted for neighbouring bars, to the undisguised joy of the rival brewery. Are "M.D., B.Sc.'s" publican friends as unselfishly philanthropic?

I am, Sirs, yours faithfully,

Honor Oak-road, S.E., Feb. 25th, 1901. H. LAING GORDON.

THE NEW SYDENHAM SOCIETY.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will allow me a little space in order to direct the attention of your readers to an advertisement which appears in your pages and to explain its bearing. The New Sydenham Society is now in its forty-third year and its last volume was numbered 172. It has a members' list of nearly 1400. In spite, however, of the indications of prosperity which these facts may serve to afford there are others which have made its council of late years somewhat anxious. Its members' list in its palmy days numbered for many years in succession more than 3000, and the decline which has of late been steady has been yet more definite during the last year. This is probably explained by the conclusion last year of its Lexicon of Medical Terms. The council believes that this decline has arisen from perfectly natural causes. The conditions of medical journalism and of the publishing trade have during the society's lifetime been greatly changed. The supply of medical literature is now very liberal and works of real merit published abroad do not now wait long for translation. The machinery of the society is such that it cannot possibly compete in promptitude with private enterprise, nor is it in the least desirable that it should attempt to do so. In brief, the *raison d'être* of the society has been to a large extent removed and the functions which it proposed to itself are now fulfilled by others. Of late the council has encountered increasing difficulty in finding works for translation which should fulfil the two needful conditions of being at once of great and permanent value and likely to be acceptable to a wide circle of readers. Works such as those of Trousseau, Hebra, Charcot, and Hirsch are no longer available. There are plenty of valuable monographs on special subjects, but they would interest only a few and their publication by the society would certainly lead to resignations of members. The works which it undertakes must be of general interest, or its numbers, and with its numbers its efficiency, will increasingly decline.

Under the circumstances described it will not cause surprise when I state that the council has had under its serious consideration the propriety of winding up the society's affairs. It possesses sufficient funds in hand to complete last year's issue of books and it has also property of considerable value in back stock. It could therefore close its life with dignity, and the present year appears to some of us a very suitable time for doing so. There are, however, not a few members of its council and other friends of the society who are strongly averse to the idea of closing its career. It need not be said that prior to any such procedure a public meeting of its members would be called with whom the final decision would rest. Before, however, taking any further steps the council has decided to submit a proposal to the profession at large, and it is in order especially to explain this that I now trespass on your space.

It was during the years in which the "Atlas of Skin Diseases" was in course of issue that the members' list was best maintained. The "Atlas of Pathology" since undertaken has not perhaps proved equally acceptable and its issue has been impeded by want of funds. The council's present proposal is to widen the scope of this latter work and to make it an "Atlas of Pictorial Illustration of all Subjects relating to Diagnosis in Medicine, Surgery, and

Obstetrics." The materials for such an atlas already collected (from all sources) are abundant, and in their selection the council would have expert knowledge at its disposal. The cost of the production of illustrations of this kind has been much reduced of late years, and from estimates which have been obtained it is calculated that if a sufficient number of subscribers could be secured four or five fasciculi of from eight to 10 plates can be produced annually and the work completed in five years. During that time the council proposes to abstain from undertaking the publication of any printed volumes with the single exception of one a year to consist of a collection of papers or lectures from foreign sources translated as promptly as possible after their publication. It may also, if funds allow, publish one or more supplements to its Lexicon. In order to ascertain the amount of support which might be expected for the proposed work a somewhat detailed prospectus has been prepared and has been distributed to all members of the profession resident in certain cities and towns. Dublin, Brighton, Manchester, and Glasgow, with a few others, have been selected. Our agent, Mr. Lewis, 136, Gower-street, will be glad to supply this prospectus to anyone applying for it (post free). In the meantime the council will be glad to receive communications from those interested in the proposal. It will be needful that a members' list of at least 2000 should be secured.

I have only to add that in case the society should not be encouraged to continue its existence and undertake the proposed atlas that it is possible that the latter may be published independently of it. There would, however, be obvious advantages in its being done by the New Sydenham Society. The present organisation would be kept going and, further, an annual volume of translated monographs would be secured.—I am, Sirs, yours faithfully,

JONATHAN HUTCHINSON,
Hon. Secretary to the New Sydenham Society.

Feb. 26th, 1901.

"GASTRIC HÆMORRHAGE AND ITS SURGICAL TREATMENT."

To the Editors of THE LANCET.

SIRS,—I am very sorry that my attention has only just been drawn to a letter on the above subject from Mr. J. Basil Hall in THE LANCET of Feb. 16th, p. 510, too late for my reply to reach you in time for insertion on the 23rd. If Mr. Hall will re-read my paper I think he will find that particular care is taken to mark the difference between so-called chronic and acute hæmorrhage, and that all my arguments are employed to try to elucidate the question of what is the best method of arresting the hæmorrhage in acute gastrorrhagia, it being taken for granted that surgical treatment is nearly always demanded in chronic but only occasionally in acute bleeding from gastric ulcer. If Mr. Hall will refer he will also notice why the second case was reported, though the bleeding was dependent on injury and not on ulcer; the reason being that I wished to give "a brief description of all the cases of hæmatemesis on which I had operated."

With regard to the facts of the case, I was sent for to operate on a perforating wound of the stomach, this diagnosis having been made because of the vomiting of blood directly after the accident. When I saw the patient I thoroughly investigated his case and personally made careful inquiries as to the hæmatemesis, both at the time, while the patient was being prepared for operation, and subsequently; so that there is no need to alter in any way the abstract in THE LANCET, taken by me from the report of the case given by my house surgeon, Mr. Levi, in the *British Medical Journal* for 1897, page 77, where occurs the following:—

> The nature of the injury is remarkable in that the perforating instrument, being somewhat blunt at the end, must have pushed aside the stomach and colon instead of perforating them, though the fact of blood having been vomited shows that the stomach must have received the impact of the file, and have suffered injury to its internal coats.

The interest of the case lies in the fact of there being no further hæmorrhage after the abdominal lavage without any operation on the stomach itself, as is stated fully in the abstracted notes. The fact of the first patient on whom pylorectomy was performed for a chronic ulcer of the pylorus that had been bleeding for some time having subsequently suffered from cicatricial contraction of the opening between the stomach and pylorus is no argument against pylorectomy having successfully combated the bleeding from a chronic gastric ulcer, on which account simply an abstract of the case is given. The subsequent history of this case is included in my statistics of gastro-enterostomy, now almost ready for publication.

Had I described, under operations for chronic hæmatemesis, the cases of slight coffee-ground vomiting so common in chronic ulcer and in cancer of the stomach, on which I have operated the list would not have been limited to the few cases given at the end of my paper; but Mr. Hall, despite his criticisms, must be fully aware that very serious bleeding, leading even to a fatal termination, may occur under the form of so-called "coffee-ground" vomit.

I see no need, therefore, because of these criticisms to alter my opinion as to the desirability of such cases of chronic hæmorrhage being considered in a paper treating of gastrorrhagia, and in this view Mr. Hall will find, if he studies the literature of the subject, that I am supported by authorities whose views are not to be lightly set aside.

I am, Sirs, yours faithfully,

Park-square, Leeds. A. W. MAYO ROBSON.

"PERSISTENT METRORRHAGIA."

To the Editors of THE LANCET.

SIRS,—Dr. J. Inglis Parsons[1] has done well in bringing forward the treatment by electricity of what he calls "persistent metrorrhagia," but as it might be supposed from his remarks that the treatment is new for such cases I think it right, in justice to the memory of Dr. Apostoli, to say that of the 24 patients I saw treated by him in Paris in May, 1887, five were cases such as Dr. Parsons describes, two being complicated by retroversion. I have found electricity most satisfactory for this condition for the last 13 years and can corroborate all Dr. Parsons says in its favour. I find, however, that shorter sittings and apparently fewer applications are sufficient. I advocate, as Apostoli did, the strongest doses that can be borne without pain and begin if possible with 100, as against Dr. Parsons's 50, milliampères.

I am, Sirs, yours faithfully,

Feb. 25th, 1901. SKENE KEITH.

"ISOLATION HOSPITALS."

To the Editors of THE LANCET.

SIRS,—You challenge me to produce any memorandum of the Local Government Board, however antiquated, which may afford some grounds for the "stamping-out" thesis. The disillusionment came too early to permit of the Board's falling into any such blunder. The attitude of the officials of the Local Government Board of that day is well exemplified by the evidence given before the Commission on Small-pox and Fever Hospitals by Dr. Thorne Thorne, the report of which Commission was presented as early as August, 1882. The Hastings Bill was then being wriggled through the House of Commons, urgency being claimed for it on the ground that, with such powers as would be obtained under its provisions, the "stamping out" of certain infective diseases—notably scarlet fever—would only be a question of time. The same brilliant promises had been, or were being, made in Huddersfield, Oldham, Bolton, Nottingham, and elsewhere, not by enthusiasts (from whom I am supposed to have borrowed my idea), but by steady-going and sometimes highly qualified medical men who had no other end in view than the stamping out of infective diseases. The evidence in question is very significant and it forms very interesting reading to-day. Here is an excerpt. Seventh day of the Commission, Jan. 6th, 1882.

> Lord BLACKFORD: You would say that whenever compulsory notification and isolation hospitals co-existed the effect has been to considerably facilitate the isolation of infectious diseases?
>
> Dr. THORNE THORNE: Yes, the effect has been considerable where there has been a good hospital and the Act was properly administered. I can give two instances which I think will be typical of that, and the first I would quote would be Leicester. In 1870 an epidemic of scarlet fever occurred, when there was no hospital, no system of registration of infectious diseases, and between the middle of September and the end of December 217 deaths resulted. The next epidemic was in 1875. A hospital had been provided, but it was only in partial use and still there was no registration of infectious diseases. Between the middle of September and the end of December in that year 31 cases were admitted to the hospital, and the deaths in the borough were 94. In 1879 the Notification Act came into operation; it unfortunately came into operation after an epidemic of scarlet fever had commenced, but it was immediately put into operation in the middle of September and between that date and the end of December 159 cases were admitted to the hospital and the deaths in the borough were only 65. A more striking case is that of Warrington. A similar Act came into operation in 1879, and towards the end of June, 1880, isolated cases

[1] THE LANCET, Feb. 23rd, 1901, p. 547.

of scarlet fever began to appear in the town, and between that date and December of that year 52 scarlet fever patients had been removed to the hospital as the result of this Act. They had been removed from 44 houses, some containing more than one family, and in those houses there were 101 children who had not had scarlet fever, yet in only one house did a second attack occur, this result being attained by the fact that notification led to immediate removal.

Now come we to Dr. Thorne Thorne's recantation. On March 24th, 1882 Question 5321, we find the Chairman asking: "I believe you wish to make some qualification of the evidence you gave upon a former occasion?"

Dr. THORNE THORNE: Yes. Referring to my evidence given in January last as to the measures taken at Leicester and Warrington I have thought it right to add some more recent evidence. ... .. I feel that the evidence I gave as regards Leicester and Warrington is open to the inference that in those boroughs the joint operation of a system for the compulsory notification of infectious diseases and the provision of a hospital for the isolation of those diseases did successfully check the spread of scarlet fever. More recent information does not, in my opinion, bear out that view to the extent I had anticipated. As regards Leicester, for example, a diminished scarlet fever mortality during the epidemic prevalence of 1879 was compared with that occurring during similar epidemics in 1870 and 1875, but the returns of the Registrar General for 1880 and 1881 point out that, notwithstanding the joint operation, since September, 1879, of a system for the notification of infectious diseases, and of a hospital for their isolation, *there has been a very long continued prevalence of scarlet fever*, and when the whole period of the latter prevalence is compared with that of the two former ones it would appear that the later epidemic has mainly differed from its predecessors *by being spread over a longer period*. Then the other instance was the case of Warrington. When I was in Warrington in 1881 I found that the epidemic appeared to have been all but checked, there being only three, four, and three cases of scarlet fever respectively admitted to hospital during the months of January, February, and March, 1881, and only four, four, and three cases notified in the borough during those several months. Since then, however, there has been a marked increase in the disease. I felt that this result did not bear out the inference which might be drawn from my previous evidence.

Question 5323: Are you aware of any sufficient reason why scarlet fever should have increased?

Dr. THORNE THORNE: No.

Dr. CARPENTER: I should like to ask if notification was carried out in Warrington to its full extent?—It would be difficult to find any place where notification had been so effectually carried out.

Question 5329: Notification has failed to "stamp out" disease at Warrington?—Yes.

On March 21st was taken the evidence of Mr. George W. Hastings, M.P., whose Bill, as I have already said, was then before the House of Commons.

Question 5112 (Dr. Carpenter): You believe that notification is required for the purpose of repressing and "stamping out" infectious diseases?

Mr. HASTINGS: Yes.

It is perfectly evident, then, that "stamping out" was the end and aim of those who originated this movement, and the idea that infectious diseases could and would be "stamped out" by such means was held largely notwithstanding the fact that there were not only no data to go upon but all previous experience (e.g., the prevalence in many hospitals of *hospital gangrene*) pointed to the fact that the aggregation of the sick—infective and other—was a mistake.

You make me say, Sirs, that "vital statistics are the third degree of comparison of unveracity." I respectfully point out that I neither said this nor anything like it. What I did say was that these were the only statistics upon which any sort of reliance could be placed. Like Mr. Jonathan Hutchinson "I distrust all statistics—no one more than I." I am not going to traverse the statement quoted from Whitelegge's book. Any man who knows and has worked with Dr. Whitelegge as I have would think twice before he tried to controvert his carefully collected facts. That "epidemics occur at more or less irregular intervals in most of the large towns" cannot, I submit, be received as a satisfactory explanation as to why preventive institutions when dealing with an infective disease each case of which can only have arisen from a previously existing case are impotent in the discharge of the functions for which they were established, even when isolating 90 per cent. of the cases.

You accuse me, Sirs, of changing my ground. Not so. If you hold that, before condemning these institutions *in toto* I ought to have backed up my condemnation by the publication of data, I shall cry *peccavi*. I hope shortly to bring before the profession the question as to what has been the effect on diphtheria of "isolation." I shall show that if hospitalism has blocked the way of sanitary progress so far as scarlet fever is concerned its effect has been infinitely worse in the case of diphtheria. I shall endeavour to prove that the way to prevent disease does not lie in the direction of aggregating the diseased. Sirs, the isolation hospital is the record achievement of misdirected effort in our time. To my certain knowledge this fact is known and recognised by many who are in the public health service. Why have so few the courage of their convictions? In what danger from what quarter does a man stand for the fearless expression of his opinions? What is the mystery?

Your readers will be interested, Sirs, in learning what views are beginning to prevail in Germany on this important question. The distinguished writer, Hueppe, hits off the situation admirably when he says (speaking of the central authority): "Instead of being always prepared to act in the spirit of preventive hygiene for the most part plods on in the good old way with 'fresh emendations to the appendix of the modified supplement of the most recent provisional administrative instructions.'" I give the views of this distinguished bacteriologist with the more pleasure because isolation hospitals had their inception in a crude and unscientific conception of the lessons to be learned from discoveries which had been made in the field of bacteriological research during the Pasteur-Tyndall-Miguel epoch. The sanitarian, impatient of tried methods—which, by-the-bye, had by no means been found wanting—and always on the *qui vive* for short cuts to the accomplishment of the ends he had in view, imagined that the royal road to disease prevention ran through that *inextricabilis error* which the bacteriologist had prepared for the medical scientist to wander in and get lost. Hueppe, in the last edition of his "Principles of Bacteriology," 1899, claims that the way to prevent the dissemination of disease germs is by improvement in the water and soil, control of the food-supply, and works of sanitation generally.

"Works of sanitation," says this writer, "act upon saprophytes and interfere with the dangerous forms of proteid putrefaction which play a rôle in intoxications and are of importance in the ontogeny and phylogeny of parasites. ..... Again, in the separation of the sick from the healthy we often overshoot the mark and the compulsory conveyance of the sick from the dwelling-place to the hospital is frequently very injurious. ..... The psychic disadvantages, also, are frequently quite considerable, and the abolition of humanity by bacteriology seems to me a step backwards. ..... Cholera convalescents, even after they have perfectly regained their health, may harbour germs for weeks ..... diphtheria convalescents may carry about bacilli for months. On this account compulsory isolation upon the basis of bacteriological findings may lead to the greatest injury. .. ... The imprisonment of healthy and convalescent individuals is an inadmissible restriction of personal freedom. ..... In diseases, too, of the character of scarlet fever we have, to the delight of martinets, done too much in the last decade in the matter of isolation. ..... The prevention of infective diseases is to be attained by combating the cause of disease," &c.

In conclusion, Sirs, let our friends of the public health profession be certain that the value of these institutions is being appraised by the intelligent section of the British public and it is a force they will not be able to resist. The individualist has been long weary of the sacrifice of the individual for the questionable good of the rest. The economist, who sees in an institution like ours a threepenny rate with no equivalent advantages, is fretting under the imposition of useless burdens, while the politician is standing aghast at the enormous growth of the municipal debt of this country in which he sees the setting in of the rot in our commercial prosperity.

I am, Sirs, yours faithfully,

Nottingham. EDWARD DEAN MARRIOTT.

*** We publish Mr. Marriott's lengthy communication because we feel it incumbent upon us to afford him an opportunity of replying to a leading article largely dealing with his views, but we do not see that he introduces any new matter quite pertinent to the controversy. He does not refer us to any memorandum of the Local Government Board which would justify the importance which he has attached to the stamping out thesis. He disclaims having written that "vital statistics are the third degree of comparison of unveracity." We refer him to the bottom of page 19 of a pamphlet which he sent us. He will there find these words, "Statistics are being pressed into the service—statistics which are notoriously the third degree of comparison of unveracity."—ED. L.

THE LIFE-SAVING STATION AT WATERLOO BRIDGE.

To the Editors of THE LANCET.

SIRS,—In the year 1872, at my suggestion, the Royal Humane Society established this station and appointed me medical officer thereto. About two years subsequently the station was, by arrangement, handed over to the Thames

Police, whose floating station was near at hand, and I was succeeded by the then divisional surgeon, Mr. Mills, of Southampton-street, Strand. I now, with much pleasure, inclose you a "return" from the superintendent of the Thames Police, showing the excellent work the station has done during the years it has been established. Having regard to the great number of suicidal and accidental drownings annually occurring in other parts of the Thames—notably Battersea, Putney, Hammersmith, &c.—I would ask you to urge the further provision of similar institutions at other parts of the river in the metropolitan area.—I am, Sirs, yours faithfully,

ARCHER FARR. L.R.C.P., L.S.A., &c.,
Late Medical Officer of Health, Lambeth,
Dip. Pub. Health (retired).

High-street, Putney, S.W., Feb. 21st, 1901.

[INCLOSURE.]

THAMES DIVISION.

Return of the Number of Cases Treated at Waterloo Pier Station during the Years 1897-8-9 (Vide Corr. No. 322034).

Year.	1 No. of persons accidentally immersed and brought to the station for treatment.	2 No. of persons who attempted suicide and were brought to the station for treatment.	3 No. of persons who were brought to the station and in each case life was pronounced extinct.	4 Total number of cases brought to the station for treatment.	5 No. of persons apparently drowned and restored to life by artificial means.
1897	8	22	10	40	1
1898	8	16	5	29	—
1899	7	13	16	36	—
Totals for three years	23	51	31	105	1

In a number of cases which cannot be included in column 5, "apparently drowned and restored to life," as there were evident signs of vitality, the sufferer would probably have succumbed to shock and immersion but for the prompt treatment by police. It is not possible to give the number of these cases from the records with accuracy.—WM. C. ROBINSON, Superintendent.

"CONCERNING CERTAIN APPARENTLY INJURIOUS CONSTITUENTS OF POTABLE SPIRITS."

To the Editors of THE LANCET.

SIRS,—In an article by us in THE LANCET of Dec. 8th, 1900, p. 1643, under the above title the statement occurs that "we made experiments upon cats, dogs, and rabbits." This statement we wish to correct in that our own experiments were only made upon cats and dogs. At the time of writing we had really in our minds not only our own experiments but those of a previous worker—viz., Cohn.[1] Our paper was intended only as a preliminary communication and experimental details will be given fully and compared with the results of others in a subsequent paper.

We are, Sirs, yours faithfully,

LAUDER BRUNTON.
F. W. TUNNICLIFFE.

Devonshire-street, Portland-place, W., Feb. 25th, 1901.

THE COVENTRY DISPENSARY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 2nd, p. 353, under the head of "The Battle of the Clubs," there are some remarks concerning the Coventry Dispensary which the staff will be glad if you will allow them to correct. It is untrue that the reply which the staff received to their memorial was that "if they were not satisfied with their position another staff could be procured to take their places." Nothing whatever was said in the reply which could be thus construed. It is also untrue that the committee do "not hand over all the money received and thus exploited them" (the staff). All the money is divided amongst the staff after the working expenses have been paid. The number present at the meeting was 108, not 160, and so far from being unanimous there was a very large proportion who refrained from voting either for or against the resolution.

I am, Sirs, yours faithfully,

W. J. PICKUP,
For the Staff of the Coventry Dispensary.

Swanswell, Coventry, Feb. 23rd, 1901.

MEMORIAL TO THE LATE PROFESSOR TOM JONES.

To the Editors of THE LANCET.

SIRS,—It is proposed to establish some memorial of Professor T. Jones in the Owens College, and it is thought that his personal friends, and perhaps others, may wish to take part in providing the necessary funds.

No appeal will be made, but the treasurer or secretaries will be glad to receive contributions from those who desire to honour Professor Jones's memory.

The exact form the memorial will take necessarily cannot be settled till the amount of the fund is known, but it has been suggested that an exhibition or prize would be a suitable record of Mr. Jones's work.

It is not desired to limit in any way the amount of individual subscriptions, and it is hoped that those who may see this letter will bring it to the notice of other friends.

Subscriptions may be sent to either the honorary treasurer or the honorary secretaries.

Among the amounts already promised are the following:—

	£	s.	d.		£	s.	d.
D. Lloyd Roberts... ...	25	0	0	R. Bowen Hogg (New Zealand)...	5	5	0
Walter Whitehead... ...	25	0	0	W. Thorburn	5	5	0
G. A. Wright	25	0	0	Henry Ashby	5	0	0
Edward Roberts	21	0	0	Joseph Collier...	5	0	0
Alfred Hopkinson... ...	10	0	0	H. R. Hutton	5	0	0
J. E. Platt...	10	0	0	W. P. Montgomery ...	1	1	0
F. A. Southam	10	0	0				

The complete total promised is over £600.

We are, Sirs, yours faithfully,

HENRY ASHBY. D. LLOYD ROBERTS.
JOSEPH COLLIER. EDWARD ROBERTS.
ALFRED HOPKINSON, K.C. ALFRED SIMPSON.
F. A. SOUTHAM.
A. MCLAREN. W. THORBURN.
JOHN D. MILNE. WALTER WHITEHEAD.
W. P. MONTGOMERY. A. H. YOUNG.

G. A. WRIGHT, Hon. Treasurer,
16, St. John-street, Manchester.

J. E PLATT,
14, St. John-street, Manchester.
F. J. H. COUTTS,
Cromar, Plymouth-grove, Manchester.
} Hon. Secretaries.

January, 1901.

"THE TEACHING OF ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—Dr. Frederic Hewitt's letter in THE LANCET of Jan. 19th, p. 212, in reply to that of Lieutenant-Colonel E. Lawrie in the number of Jan. 5th, p. 64, is chiefly characterised by the fact that it is in no way the answer it purports to be. If I may venture to sum up the letters it would be in some such way as this. Lieutenant-Colonel Lawrie says essentially that chloroform administered in a definite way may be given with safety by the ordinary man; while Dr. Hewitt says that chloroform as given in Britain by the ordinary man is very fatal (an undoubted fact, but scarcely an answer), and he hints that this is the effect of climate and not of the method of administration—or, at least, that is what I take his reference to "sunny Hyderabad" to mean. The intention of this letter is to lay stress on Lieutenant-Colonel Lawrie's statement that the effect of the London teaching is to tend to make the anæsthetist incompetent through fright, for I can testify from personal experience as well as from personal observation of the terror with which many recently qualified men in London approach the administration of chloroform, believing as they do that death may occur suddenly and inexplicably from syncope. My own experience was distressing until I realised that if chloroform could be given in India and in Edinburgh with confidence and safety by using a particular

method, it would be my own fault if I could not give it equally confidently and safely in London by using the same method; and so far as it went (some 300 anæsthetics only in London) the experiment, I believe I may say with entire truth, was a complete success.

Dr. Hewitt's observation on the number of deaths in Scotland is irrelevant, for he produces no proof that the drug was administered by Syme's method. *The method is everything.* By all means let the present scandal of sending out men to practise as fully qualified without practical knowledge of the giving of anæsthetics cease, but at the same time do not expect the present rate of mortality from chloroform to drop in Britain so long as the method of administration is that now in vogue. For several years I have been looking in the columns of THE LANCET for the description of a case of death from chloroform poisoning due to heart failure, but although many have purported to be so not one has borne investigation. If this is solving the chloroform problem clinically there are some who may differ from Dr. Hewitt in considering the solution final at present.

I am, Sirs, yours faithfully,

CLAYTON LANE, M.D. Lond.,
Captain, I.M.S.

Calcutta, Feb. 7th, 1901.

THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 582.*)

The Demand for an Increase for Family Contracts.—The Appointment of a Solicitor as General Secretary.—The Systematic Method of Proceeding.—The Strike and its Success.

THE incident which acted as a special stimulant in bringing about the formation of the Northumberland Medical Association was the fact that the Backworth colliery surgeons had of their own initiative demanded 9*d.* instead of 6*d.* per family per fortnight. In answer to this large bills were put into circulation announcing that "The Backworth and District Medical Coöperative Association" were going to give advice from fully qualified medical practitioners with medicines of the best quality procurable, that the time of attendance at the surgeries would be arranged to suit the convenience of the public and to prevent patients having to wait, that in serious cases expert advice would be obtained on the recommendation of the medical officer of the association entirely free of cost, that water-beds, air-cushions, and other appliances would also be provided, and that there would be a trained and certificated nurse at the disposal of the members. All these multifarious advantages were to be secured by the modest payment of 6*d.* per fortnight, not for one individual, but for a whole family. It is true that 6*d* per fortnight per family is generally the sum paid by miners for medical aid in this district. But this sum is very often paid direct to the colliery surgeon. There is no organisation, no coöperative society or medical aid company, no lay committee of management acting as intermediary and sometimes taking upon itself to reprimand its medical officer. The more general arrangement is that the cashier who pays the wages to the miners deducts the sum they consent to pay to their medical attendant. But here was a coöperative society stepping in between the surgeon and his patients and proceeding to advertise in a tradesman-like manner. Though at that time the Backworth practitioners had no organisation to support them they determined to resist, and they sent in notice that they would not undertake to attend a whole family for less than 9*d.* per fortnight. The Backworth and District Medical Coöperative Association at once concluded that they would be able to import a medical officer, and they advertised in several papers. But by the time these advertisements appeared the Northumberland Medical Association had been formed and it immediately inserted counter advertisements advising that no one should go, but should first communicate to the association for information as to the dispute at issue. Also, considerable pressure was brought to bear to prevent anyone taking the place of the Backworth practitioners. The Backworth and District Medical Coöperative Association were able to import a medical practitioner, but before they achieved this they had been several weeks without any medical men working under contract. When a case of illness occurred the patients were obliged to seek the advice of a practitioner in the neighbourhood and were treated as private patients and charged the usual 2*s.* 6*d.* fee. The patients, however, did not pay this fee; it was the committee of the Backworth Coöperative Society that undertook to settle these accounts. In one case the amount due reached a considerable sum, but the account was purposely reduced to £50 so that the matter might be brought before a county court. The Northumberland Medical Association financially supported the Backworth practitioner to whom this sum was due, for in the meanwhile he had become a member of the association and the verdict was in their favour, and the miners had to pay the account and the legal costs. This verdict and the unsatisfactory result of importing an outsider finally broke up the Backworth and District Medical Coöperative Association. The miners now consented to pay 9*d.* instead of 6*d.* per fortnight for each household, and thus the medical men, after a struggle that did not last very long, were completely successful.

While this struggle was proceeding the Northumberland Medical Association amalgamated, as already described, with the Newcastle Medical Ethical Society and began to shape out its policy. One of the first points agreed upon was that throughout the county the fortnightly subscription should be 9*d.* and not 6*d.* for a family. Then circulars relating to the Broomhill medical aid organisation showed that there was a good deal of advertising practised in that locality. A deputation from this body was brought to Newcastle and they promised to cease advertising and canvassing. As for paying 9*d.* this they were also willing to do, but they wanted to provide a nurse and for this purpose proposed to deduct 1*d.* from the 9*d.* Then they were in the habit of taking 25 per cent. from the remaining 8*d.* and providing the drugs themselves. Doubtless this meant no loss as the drugs would probably cost 2*d.* out of the 8*d.*, but the objection is to intermediaries between the medical man and his patient. In the mining districts there is no need of societies to organise medical aid and, generally speaking, to manage the medical man's business for him. The paying cashier at the pit's brow collects the subscription as he pays the miners their wages and the colliery surgeon can quite well attend to all the rest himself. In regard to the particular case at Broomhill the matter for the moment stands in abeyance; canvassing and advertising have been abolished, the 9*d.* is paid, but subject to the deductions mentioned.

In regard to the miners in general, the first step has been to secure unanimity, not only among the colliery surgeons concerned, but also throughout the neighbourhood. Thus in six colliery districts on the north bank of the Tyne the 18 surgeons engaged were hesitating, but the President of the Northumberland and Newcastle Medical Association wrote personally to each surgeon and called upon some of them and by persistent personal effort induced them to sign and promise to observe the rules of the association. Counting the practitioners of the outlying districts who might have come in and done some of the work of the 18 colliery surgeons 36 signatures in all were obtained for this neighbourhood. All being now ready the 18 colliery surgeons were not exposed to the unpleasantness of entering upon a dispute with the miners among whom they live. It was from Newcastle that the communication was made and by the general secretary, Mr. Garforth Drury, who is a solicitor. The appointment of a solicitor as the secretary of a medical union is a new departure, but there is a great deal to be said for it. In this the Northumberland practitioners followed the example of the County of Durham Medical Union and the work is likely to be done in a business-like manner and there is less chance of committing some legal blunder. Then there are the office, the clerks, and everything necessary available every day. The communication made was worded as follows: "We have been requested by the council of the Northumberland and Newcastle Medical Association to apply on behalf of their members for a fortnightly payment from the members of"—here followed the names of the miners' organisations or collieries—"of 9*d.* from all householders and married men for medical attendance. The members of our association in your districts are," and here followed the names, not only of the 18 colliery surgeons, but of all the surgeons in the outlying districts, making 36 names in all. After this display of unanimity the notification continued: "And we are

requested to give you a fortnight's notice from the date hereof, after which time they will, as members of this association, be under an obligation to us not to accept less than the above rate. The reasons we advance for this rise in fees are: (1) the illegality now of employing any but qualified and registered medical men as assistants; (2) the increased cost of medical education, which now takes five years to complete instead of two and a half years; (3) the increasing difficulty of obtaining, and greater cost of, assistants' services; (4) the greater cost of drugs and surgical dressings; and (5) the increasing use of expensive instruments."

It will be seen that the whole responsibility is assumed by the medical union. The local practitioner who gives in his resignation is but a pawn in the game; he refers the miners' committees and all their deputations to the Medical Association. It is Mr. Rutherford Morison who, as President, has to answer all the objections and to receive all the abuse; but, generally speaking, the miners have recognised that the demands made were fair and just. In two places, however, on the north bank of the Tyne there has been opposition. In the first of these the resistance was very virulent. The men would not pay the 9*d*. and the colliery surgeons had to request the cashier at the colliery offices not to accept any men under 9*d*. Thereupon a deputation was sent to Mr. Morison asking him to put off the matter for a month, and after much discussion he consented to a postponement for a fortnight. This delay terminated with the end of last year and then another fortnight's prolongation was accorded so that Mr. Morison might go to the district and address a meeting of miners so as to explain the matter to them. Here he was pretty sharply heckled and the next thing that occurred was the publication in various newspapers of an advertisement inviting medical men down to the district. The Medical Association at once published counter advertisements urging medical men not to go to this district. Nevertheless, some applications for the vacant post were made and the miners accepted two medical men. The first candidate, however, failed to put in an appearance; the second had settled upon the day of his arrival, but Mr. Morison succeeded in obtaining his address and wrote to him at length. According to the answer received this medical man had been misinformed as to the true state of affairs and now promised not to go. Subsequently another practitioner accepted the offer, but telegrams were sent to him by the President of the Medical Association and his arrival was also stopped. Now it is reported that someone else is coming and letters and telegrams have been despatched to warn him off. but the result is not yet known. This local strike has lasted some three weeks and Mr. Drury has written to the local practitioners to say that he will support them in county-court actions against their patients who do not pay the 2*s*. 6*d*. fees. Thus the method of action is first thoroughly to blockade the district and to prevent the arrival of any outside help, and then to county court all patients for 2*s*. 6*d*. fees till such time as they consent to contract for 9*d*. instead of 6*d*. per fortnight per household.

In the second district where resistance has been offered the miners, as explained above, offered to pay the 9*d*., but wanted to provide the drugs themselves and to deduct a portion of the money for that purpose. Here the objection is against the formation of lay committees acting as intermediaries between the practitioners and their patients. Altogether and up to this date applications have been made in 17 collieries, and in 13 cases the increase of remuneration was acceded to without demur. In at least three out of the four other cases the Northumberland and Newcastle Medical Association has succeeded in preventing any outside practitioners answering the advertisements published and taking up the vacancies. Thus the efforts made have been, on the whole, very successful, a success in which the miners themselves have largely contributed by the reasonableness and fairness which they have shown in the vast majority of the cases.

Newcastle, Feb. 25th.

PREVENTION OF PHTHISIS.—A public meeting of the Gloucester, Somerset, and Wilts Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis will be held at the Guildhall, Bath, on March 6th, under the presidency of the mayor, when an address will be given by Sir James Crichton Browne.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Health of the City.

THE report of the medical officer of health, Dr. Alfred Hill, for the fourth quarter of the year 1900 presents some interesting details, among others an exceptionally low birth-rate and an unusually satisfactory death-rate, the former being 29·4 per 1000, the latter 18·2 per 1000. Certain parts of the city show marked contrasts. Dr. Hill points out that the value of the zymotic death-rate has been greatly depreciated in recent years by the use of the term "enteritis" as a synonym for diarrhœa and expresses the hope that in future the complaint will be certified as due to "zymotic" or "epidemic enteritis." The cases of diphtheria were less numerous; 30 of those reported occurred in the Blue Coat School, the scholars having to be disbanded. A recurrence took place among a few scholars on their return. Advantage was taken of bacteriological knowledge for no less than 455 specimens from the throats of the scholars were examined at the University laboratory. Certain sanitary defects in the school were remedied and no more cases happened.

The Mond Gas Scheme.

Questions of health and comfort are closely connected with purity of the atmosphere. This depends largely on the commercial undertakings in manufacturing areas. In and around this city are many large works and manufactories which contribute greatly to the vitiation of the surrounding air by pouring forth dense volumes of smoke and emitting fumes of a noxious and disagreeable character. Some of these evil results, it seems, may be combated and rendered far less detrimental by the aid of scientific discoveries of recent date. The subject was discussed on Feb. 21st at an important meeting of those interested in the industrial life of the Midlands. The object of the meeting was the consideration of the Bill now before Parliament for conferring powers upon the South Staffordshire Mond Gas (Power and Heating) Company. It was stated upon high authority that the introduction of this gas into the district would be an enormous benefit and advantage, because the gas could be made cheaply and the sulphate of ammonia contained in the fuel could be preserved instead of being thrown away as it has been for so many years. It would be suitable for driving machinery and would save all cost of stoking and clearing away ashes, besides being free from tar and dust. It was stated by Sir Alfred Hickman that the use of Mond gas as compared with ordinary gas was analogous to the use of charcoal as compared with coal. Principal Lodge of the Birmingham University expressed his opinion that so long as they continued to burn crude coal in a fashion which he condemned as barbarous and half-civilised so long would the chimney shed its sombre shadow on our industrial existence. It may be the beginning of an evolution in our town life if the promoters of this scheme realise their aspirations in the project before them.

The Value of District Nurses.

The twenty-ninth annual meeting of the friends of the Birmingham District Nursing Society was held on Feb. 19th under the presidency of the Lord Mayor (Alderman Edwards). The report showed that during the past year 2501 cases were nursed and 57,432 visits were paid by the society's nurses. The expenditure had increased and an adverse balance of £40 was shown. The value of the work done was pointed out in forcible terms, and also that while the work had greatly increased the number of nurses had not been increased in proportion owing to the want of adequate funds. The comparison with other large towns, such as Manchester and Liverpool, in this particular kind of nursing showed that Birmingham was much behind. Thus in Manchester and Salford there were 55 nurses and five homes, while in Birmingham with much the same population there were 17 nurses only. The subscriptions in the two places were notably different, Manchester raising some £3000 per annum, while Birmingham secured only £579 for the same purpose. Various remedies were proposed which may be successful in placing this useful institution upon the better footing which it deserves.

Feb. 26th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Tropical Medicine: Health and Sanitation in West Africa and the Tropics.

A LARGE and influential meeting was held at the Town Hall on Feb. 12th under the presidency of Mr. Alfred L. Jones, in connexion with the School of Tropical Medicine, "to consider the subject of health and sanitation in West Africa and the tropics in the light of the researches of the three malaria expeditions of the School of Tropical Medicine." Among those present were Sir William S. Church, Bart., the Lord Bishop of Liverpool, Principal A. W. W. Dale of University College, Dr. F. W. Mott, F.R.S., &c. Sir William Church said that two years ago he had the pleasure of being present at the inaugural gathering of the School of Tropical Medicine, and he was pleased to find himself at the present meeting. Referring to the enthusiastic manner in which the movement had been taken up alike by members of his own profession and by leaders of the commercial interests it naturally followed that success was assured. Sir William Church congratulated the school upon its wisdom in sending out three expeditions to the West Coast of Africa and a fourth was now engaged in studying a not less dreadful foe to mankind than malaria in its own haunts. Professor R. W. Boyce said in justification of the wisdom which had originated the movement that three West African expeditions had come back heaped up with results which were now becoming classical. Commercial schemes would have a far greater chance of success from the results of the researches which had been, and were yet to be, undertaken. Speaking of the untimely death of Dr. Walter Myers at Parà in Brazil he said it came to himself as a great shock, particularly as he was responsible for Dr. Myers becoming a member of the expedition. He hoped that they would have not only a thoroughly well-endowed chair of tropical medicine in memory of the late Dr. Myers, but also scholarships connected with it. The Bishop of Liverpool also addressed the meeting and paid a handsome tribute to the citizens of Liverpool for their enterprise in establishing a school of tropical medicine. Major Ronald Ross, late I.M.S., in an interesting address dealt with the three expeditions to the West Coast of Africa. He advocated the importance of Europeans living at a distance of at least half a mile from the huts of the natives, and effectual surface drainage around the European quarters. He also pointed out that the only safe supply of water in the country was the rain. He hoped some day to see tracts of West Africa rendered by careful sanitation as healthy as India.

The Health Committee and the Lady Sanitary Inspectors: the Voluntary Notification of Phthisis.

From a report of the proceedings of the Health Committee it would appear that some members of the committee are sceptical of the value of the services of the lady sanitary inspectors. Alluding to a shocking case of child neglect and domestic squalor reported in the local papers, Alderman Ruddin, J.P., asked what the lady inspectors were doing. He understood that the female inspectors were intended to take notice of such cases. Alderman Roberts said that he thought when these ladies were appointed they would go into the houses of the poor and that the city would get rid of all squalor, crime, and child neglect. The chairman said that there were only eight lady sanitary inspectors. They visited the houses of the poor in the lower parts of the city and gave instructions in domestic matters and the care of children. They reported daily to the medical officer of health. It was an important but difficult work and the ladies were working very hard and, thanks to their tact and kindness, they were now generally well received. Their efforts had already had a good effect on the health of the poorer localities. The cost of the lady inspectors is about £12 per week.—The medical officer of health (Dr. E. W. Hope) has issued a circular letter stating that in future a fee similar in amount to that payable under the Infectious Diseases (Notification) Act will be paid in respect of all cases of phthisis notified in which disinfection of rooms or clothing, or other action on the part of his department, is indicated as desirable. Hitherto no fees have been paid for the voluntary notification of cases of phthisis.

The Lord Mayor's Hospitals Century Fund.

The Hospitals Century Fund initiated by the Lord Mayor for the liquidation of the debts upon the hospitals of the city has now reached £10,016 9*s*. Upon the receipt of a further sum of £130 it is the Lord Mayor's intention to distribute to the charities at the rate of 10*s*. in the pound.

Bequests to Liverpool Charities.

By the will of the late Mr. William Henry Shirley of Allerton, retired steamship owner, who died on Jan. 31st, 1901, the following Liverpool charities will benefit: the Royal Infirmary, £5000; the Liverpool Dispensaries, £4000; the Infirmary for Children, £1000. The David Lewis Northern Hospital, the Royal Southern Hospital, and other charities are also included as legatees.

The Hospital for Cancer and Skin Diseases: an Unenviable Situation.

IN THE LANCET of Feb. 6th, p. 513, reference was made to the friction which again unfortunately exists at this hospital. Further developments, following upon the rejection at the annual meeting of Colonel John Pilkington, the chairman of the committee, have now taken place. As a protest against the exclusion of a gentleman who had used every endeavour to further the interests of the charity, Dr. W. T. Blackledge and Dr. S. Mathews, two of the assistant medical officers, have resigned their appointments. Four members of the committee, including Alderman Grindley and Colonel Frank Walker, have also resigned, as well as the matron, the sister, and all the nurses. Even the domestic servants have declined to be further connected with the institution. Colonel Pilkington, the late chairman, took a great interest in the management of the hospital and was chiefly instrumental in framing new rules and regulations based upon those of the principal hospitals in Liverpool, London, and Dublin. Dr. W. T. Blackledge's name is specially mentioned in the report recently issued to the subscribers at the annual meeting for the creditable manner in which he had performed the additional duties imposed upon him by the absence of his senior at the seat of war. As this charity receives subscriptions and donations from the public an independent and searching inquiry into the whole question is urgently called for.

Feb. 26th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Isolation Hospital at Pontypridd.

AS long ago as May, 1895, Dr. William Williams, the medical officer of health of the county of Glamorgan, in a special report upon the isolation hospitals within the county urged the necessity for such an institution at Pontypridd, and from time to time during the subsequent years the urban district council have been reminded of their responsibilities in this direction. In the report referred to Dr. Williams advised that the urban and rural districts might with advantage combine in the erection of a joint hospital. The area of the combined districts is 25,000 acres, with a population of about 50,000 persons. As there appeared to be no prospect of any satisfactory arrangement being made between the two district councils, the urban council have at last decided to build a hospital to serve their own district alone where there is a population approaching 42,000. The Local Government Board have been asked to sanction a loan for £7930, a sum which it is estimated will cover the cost of the site of the hospital, the buildings, and furnishing. There will be an administrative block, two ward pavilions with 10 beds in each, and a laundry and disinfecting block. It is not proposed to erect an observation block and as provision is only made for the treatment of two diseases at one time the accommodation can hardly be said to be adequate for the needs of the district, which is essentially of a working-class character.

Merthyr General Hospital.

The Merthyr General Hospital was established in 1887 with 29 beds and has always been in the fortunate position at the end of each succeeding year of having a balance upon the right side, so that a sum of nearly £600 has accumulated. In 1899 the balance of income over expenditure was £92 and last year it was £39. The total income for 1900

amounted to £1400 and the weekly cost per bed is said to be under £1. During last year 222 cases, including 81 accidents, were treated in the hospital. At the annual meeting of the supporters of the institution held on Feb. 20th Sir William Thomas Lewis was elected president in succession to the late Marquis of Bute, who had during his lifetime contributed from time to time sums amounting to £3000 towards the erection and establishment charges of the hospital. It is proposed to increase the accommodation in the nursing home and to light the entire buildings with electric light.

Health of Aberystwith.

The medical officer of health of Aberystwith states in his annual report that there were only 19 cases of infectious disease notified to him during last year, but he considers that the circumstances surrounding some of the cases showed the need of an isolation hospital. At Llandudno a fever hospital was established in 1881 and in 1897 was enlarged to accommodate 26 patients. It is quite as necessary for a health resort which desires to hold its own among its rivals to provide an isolation hospital as it is to erect a pier or a promenade, and the Aberystwith Corporation will be well-advised if they speedily give effect to the recommendation of their medical officer of health.

Swansea Workhouse.

Upon the resignation early in the year by Mr. D. Howell Thomas of his Poor-law appointments in Swansea the board of guardians decided to divide his district into two portions and to appoint for the town portion and the workhouse a medical officer at a salary of £250 per annum. This combination is not viewed with favour by the Local Government Board. The Board think that it will not permit of systematic attendance at the workhouse and suggest that an assistant medical officer shall be appointed for the workhouse alone who shall reside in or near the establishment and devote his whole time to his duties, while the medical officer for the town district shall act as medical officer for the workhouse for consulting purposes only. The board of guardians have not yet come to any decision in the matter.

Devon and Exeter Hospital.

The annual meeting of the subscribers of this institution was held on Feb. 21st. The medical report stated that 1219 in-patients had been admitted, against 1322 in 1899. The out-patients numbered 5067, compared with 4303 in the previous year. The average daily number of in-patients was 141. The financial statement showed that the total receipts amounted to £12,781 and the expenditure to £14,555. The total deficit of the hospital at the end of 1900 amounted to £2402. The President (Mr. W. Buckingham) made a strong appeal for increased support to the institution and added that the unfavourable balance would be met by realising a legacy from the late Miss S. Northcote of £3000.

Feb. 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Asylum for the Insane.

THE annual meeting of the corporation of this institution was held in the City Chambers on Feb. 25th, Sheriff Rutherford presiding. In their annual report the managers referred to the fact that Queen Victoria was for 60 years patroness of the corporation, and that in 1841, when her Majesty bestowed on them this honour, there were only 39 patients. During the year 1900 the number of patients under treatment in the asylum averaged 940, including 377 private patients, for whom various scales of charges existed, and 563 patients chargeable to parochial authorities. The ordinary revenue amounted to £57,139, and after all payments were made there remained a free surplus of £3601. The cost per head of the pauper inmates during 1900 was £31 14*s.*, against £32 11*s.* for the year 1899, the greater part of the decrease being due to the distribution of the fixed charges over a larger number of patients. The number of pauper patients at Morningside was greatly in excess of that for which the asylum was designed. It was probable that more than a year must elapse before the new district asylum was ready for occupation, and the managers could not without anxiety contemplate the prospect of having to find accommodation for the ever-increasing number of paupers. Dr. Thomas S. Clouston, the superintendent, in submitting his annual report said that the past year had been a record one for admissions, the number being 38 over the average of the past five years. The increase had been entirely in rate-paid cases, chiefly from Edinburgh, of whom 400 were admitted during 1900, a number which was 68, or 20·5 per cent., over the average for the past five years. In seeking for an explanation of such an increase of insanity among artisans and labourers he was inclined to think that the excessive use of alcoholic liquors during prosperous times was to a great extent the exciting cause. The new Inebriates Act was almost a dead letter. On the general question of the increase of mental disease in the country Dr. Clouston said that in the 20 years 1880–1899 the accumulated aggregate of patients paid for from private sources had increased only 378, or 16 a year, over what the increase of population would account for; but in the case of the rate-paid patients the increase in the accumulated aggregate had been 2646, or 124 a year, over what the increased population would account for. In the northern and Highland counties, which were either rural or bordering on the sea, the increase had been 80 per cent.; while in the rest of Scotland it had been 42 per cent., and in Edinburgh there had been a slight decrease relatively to the augmentation of population.

Glasgow Royal Infirmary.

IT is understood that negotiations are proceeding between the managers of the Jubilee Committee regarding the financial obligations of the reconstruction scheme. In the meantime the Glasgow Archæological Society, influenced, presumably, by the verdict of the Institute of Architects, has passed a resolution protesting against the adoption of any design likely in any degree to impair the æsthetic effect of the neighbouring cathedral. The society expresses the opinion that the present elevation of the infirmary is "dignified and suitable to the locality." Apart altogether from the question of the practical value or otherwise of the new plans it is felt in many quarters that it would be a mistake to remove the front elevation of the present building. This possesses both historic and architectural value and its loss would be inadequately compensated for by the substitution for it of a brand new Jubilee porch.

The Small-pox Epidemic in Glasgow.

In consequence of the reduction in the number of cases of small-pox in Glasgow an official statement will in future only be issued once a week. The latest bulletin appeared on Feb. 23rd, when the cases in hospital numbered 355. Dr. A. K. Chalmers in his report attributes the shrinking of the epidemic to the widespread recourse to revaccination which has occurred during recent weeks. He warns the public that the danger is not yet over and commends the action of the corporation in recommending revaccination as a condition of service in the various departments. The report also contains a fairly plain hint that the standard of domestic and personal cleanliness in many districts of the city falls far short of what is necessary both for individual and public well-being.

Microscopical Society of Glasgow.

At a meeting of this society on Feb. 21st Professor John Glaister lectured on "The Intercommunicable Diseases common to Man and the Lower Animals." The lecture dealt with the principal diseases capable of being transferred from animals to man and was illustrated by an excellent series of preparations and micro-photographs. On the motion of the chairman, Dr. Rankin, Professor Glaister received a cordial vote of thanks.

Success of Glasgow Students.

Much satisfaction is felt in medical circles at the announcement that at the recent examination for the Indian Medical Service the first place on the list was gained by Mr. Anderson G. M'Kendrick who is a Glasgow graduate and a son of the popular professor of physiology. Dr. Norman Scott, who gains the fifth place in the competition, is also a graduate of Glasgow University.

Unusual Legal Case.

A case of a somewhat unusual character recently came before the Glasgow Police-court. It appears that three adults residing in a house from which a man suffering from small-pox had been removed to hospital refused either to be revaccinated or to go to a reception house. The police authorities therefore applied to the magistrate for a warrant to authorise their detention and this was accordingly granted.

Dr. Chalmers, who gave evidence, said that the house consisted of only two apartments and could not be properly disinfected while people were occupying it.

Medical Officer for Paisley.

Dr. Alexander Robb of Hamilton has been appointed medical officer of health of the burgh in succession to Dr. William Robertson, who has received a similar position at Leith.

Feb. 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal University of Ireland.

AT a meeting of Senate of the Royal University of Ireland, held on Feb. 21st in Dublin, among other matters the following resolution was unanimously adopted:—

That, in the opinion of the Senate, the relations of the University with its own colleges and students and with other colleges and students are unsatisfactory, and that it is most desirable that a Royal Commission should be issued to inquire into the working of this University as an examining and teaching body in relation to the educational needs of the country at large, and to report as to the means by which university education in Ireland might receive a greater extension and be more efficiently conducted than it is at present.

If the Government, acting on this suggestion, appoints a Royal Commission the whole question of Irish university education will again be thrown into the melting-pot, and if only some stable condition of affairs arise instead of the present uncertainty the inquiry will do good. I understand that the Senate have also taken action on another important question. There have been constant complaints about the character of the examinations in medicine not only in the Royal University, but in its predecessor, the old Queen's University. The examiners are now instructed to confine their examinations to the subjects treated in the text-books in common use in the medical schools of the kingdom and to the cases met with in ordinary hospital practice. Clinical examiners will not be allowed to examine candidates on cases under their own care. In addition to these excellent instructions the Senate passed resolutions unanimously to appoint for the October examinations extern examiners in surgery, midwifery, ophthalmology, and pathology. It is obvious that these examiners must be men of standing and experience not connected with any of the Irish medical schools.

Londonderry Infirmary.

Mr. Lee Hogg has proposed to fit out at his own expense the waiting room and extern department for the infirmary in Londonderry.

Feb. 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Impure Water-supply to Hospitals.

AT the Hospitals Medical Society, a meeting of which was held on Feb. 1st, M. Troisier remarked that as hospital reform was in the air it was interesting to note that the water laid on to the Paris hospitals was in many cases drawn from impure sources. Close to his own wards there were three taps. Two of these delivered water from the Seine and one water from the Dhuys. It was quite certain that only too often the patients and even the nurses drew water from the tap nearest to hand without looking at the labels over them. One of M. Troisier's patients had to have his stomach washed out. This was done with impure water and on the thirty-sixth day of his stay in the hospital he developed typhoid fever. M. Ballet replied that typhoid fever could be caught in the most unexpected ways. Thus a delirious patient of his used to have baths. Sometimes she would disappear under the water dragging with her the nurse. They both developed typhoid fever on the same day. M. Letulle said that the matter was worthy of the strictest attention. At the Boucicaut Hospital, which is quite new, seven cases arose. Of these three were patients, two being pregnant women and one a case of tuberculosis. Besides these there were four nurses, two from the lying-in wards and two from the medical wards. Of these women five could not have been infected from outside—namely, the three patients and the two lying-in ward nurses, for they had never seen a case of typhoid fever. Only the two medical nurses could have been infected directly. Thus five out of seven cases were probably due to the impure water.

Hæmatemesis during Appendicitis.

At the meeting held on Feb. 12th M. Dieulafoy read a paper before the Academy of Medicine on the cases of a certain number of patients who had suffered from hæmatemesis during attacks of appendicitis. M. Dieulafoy said that the complication must be fairly frequent, as he himself had seen six cases in less than a year and various other observers had published accounts of the same thing. The hæmatemesis is always ushered in by nausea and bilious vomiting; it attacks children as well as adults and commonly recurs two or three times at short intervals. Moreover, it is very often fatal. The quantity of blood brought up at each attack is very considerable—namely, 200, 300, or as much as 800, grammes. It sometimes comes up in a liquid condition and at other times as clots of a deep black colour. The attacks occur almost without exception in persons who have been operated upon too late and is as a matter of fact a manifestation of a general infection. That this is so is proved by the fact that the attack is preceded by other symptoms of toxæmia, such as jaundice, urobilinuria, albuminuria, and the like. It is the discharge of this toxic principle by the gastric mucous membrane which gives rise to the hæmorrhage, the immediate cause of which is small ulcers which are generally situated in the neighbourhood of the pylorus. The conclusion which M. Dieulafoy drew from these facts is that appendicitis is an infection which is a menace to the whole organism. The chances of a cure are greater in proportion to the early removal of the focus of infection.

The Therapeutics of Lecithin.

M. A. Gilbert and M. L. Fournier communicated a paper to the Society of Biology at the meeting held on Feb. 9th on the Therapeutics of Lecithin in the Human Being. Most observers agree in attributing to this substance a considerable rôle in the process of nutrition and as favouring the assimilation of nitrogen and of phosphorus. The lecithin which M. Gilbert and M. Fournier employed was obtained from the yelk of eggs. Given to animals in the laboratory, whether by the mouth, by subcutaneous injection, or by injection into the peritoneal cavity, in doses of from two to five grammes at a time or in small doses such as 0·10 to 0·20 of a gramme, long continued, it appeared to be absolutely devoid of any toxic quality. The animals gained rapidly in weight, a fact which was very noticeable in young animals which rapidly overpassed the controls in weight. M. Gilbert and M. Fournier gave lecithin to patients by the mouth in the form of a pill in doses of from 0·05 to 0·15 of a gramme every two days. In the case of some patients with advanced tuberculosis either on one or both sides they obtained the following results. The appetite and strength improved and the weight went up in spite of high fever which existed in one case. In two cases the cough became less frequent, the expectoration lessened, and the quantity of bacilli in the sputum diminished. M. Gilbert and M. Fournier have also given lecithin to patients suffering from neurasthenia and other forms of nervous disease but found it difficult to draw any definite conclusion from the results obtained. In general, however, they thought that the appetite and general health improved. They finally concluded (1) that the prolonged administration of lecithin is no more harmful to man than to the lower animals; and (2) that the therapeutic results so far obtained, although not complete, are yet encouraging and justify the use of lecithin in the human being.

Carbonic Oxide Poisoning.

A defective stove has again been the cause of a terrible catastrophe. Nearly all the inmates of a hospital ward have been poisoned by the emanations from an apparatus of this kind. One of the wards in a private asylum at Noisy le Sec, near Paris, contained nine beds. Of the occupants of these seven were found in the morning to be dead, and of the two who were still alive one has since died. The inquest showed that, according to the evidence of the survivor, the fault lay entirely with the patients. The stove was always put out at 8.30 P.M., but the patients who had been complaining of the cold smuggled in some charcoal during the day and charged the stove afresh after the departure of the nurse. They filled it so full that they raised up the lid of the stove and so the gases escaped into the room with lethal effect.

Feb. 26th.

Obituary.

WILLIAM JAMES FLEMING, M.D., F.F.P.S. GLASG.

WE regret to announce the death of Dr. W. J. Fleming of Woodside-terrace, Glasgow, which took place on Feb. 25th. The deceased, who was only in his fifty-second year, received his medical education at the Universities of Glasgow and Edinburgh. In 1872 he became qualified as M.B. Glasg. and L.F.P.S. Glasg. In 1875 he was admitted F.F.P.S. Glasg. and in 1879 he proceeded to the degree of M.D. An industrious and energetic worker, he made several contributions to medical periodicals, one of them being an article on the Treatment of Disease of the Spinal Column, which appeared in THE LANCET of April 27th, 1889.

Our Glasgow correspondent has sent us the following appreciative notice of Dr. Fleming's work and character: "During the whole of his professional life Dr. Fleming has been well known in medical circles and has taken a prominent part in hospital work and medical teaching. Commencing his career as a lecturer on physiology in the Royal Infirmary School of Medicine, he afterwards became surgeon to the infirmary and at the end of his term of service was elected to be one of the managers of the institution by the Faculty of Physicians and Surgeons. In this latter capacity he took deep interest in the proposed scheme of reconstruction, and his influence in securing a sounder recognition of the position of the visiting staff was much appreciated by the profession. Besides teaching clinical surgery at the Royal Infirmary he was at various times lecturer on surgery at Queen Margaret College, examiner on the same subject in the University, and surgeon to the Royal Hospital for Sick Children. He was also for a number of years a member of the examining board for the Scottish triple qualification. Personally, Dr. Fleming commended himself to his friends by a gentleness of heart which from the stranger was concealed by a manner that seemed to be free from all sentimental leanings. But his practical kindliness was as sincere as it was unostentatious. To all his *confrères* he was known for his undeviating straightforwardness and honesty of purpose. He has left behind him in many hearts a sense of personal loss which will not readily be extinguished and more than one medical institution is his debtor for public service rendered with resolute courage and unquestioned rectitude of motive."

JAMES NICOL, M.D. GLASG., J.P.

BY the death of Dr. James Nicol, which occurred on Feb. 20th, Llandudno has lost one of its oldest and best known residents. Dr. Nicol was born at Carnwath, Lanarkshire, in 1815, studied medicine in Glasgow and Edinburgh, and graduated as M.D. of Glasgow University in 1839. He commenced practice in Carnwath, but in 1858 removed to Llandudno where he made a special study of the climate and instituted systematic meteorological observations which have been carried on continuously up to the present time. For about 20 years he held the appointment of medical officer of health and in this capacity he was able to accomplish much in the way of improving the sanitation and the water-supply of the place. The building of the pier and the laying out of the road round the Great Orme were also largely due to his energy and public spirit. Dr. Nicol was the author of small treatises "On the Climate of Llandudno," "Bathing, its Principles and Practice," and "Llandudno as a Health Resort." He was a Member of the Scottish Meteorological Society, a Fellow of the Royal Meteorological Society of England, and a Justice of the Peace for the county of Carnarvon.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Hermann Pfeiffer of Darmstadt, formerly Director of the hospital there and author of many memoirs on Hygiene. He was 71 years of age.—Dr. R. B. Cole, Professor of Midwifery and Gynæcology in the University of California, San Francisco.—Dr. H. Shapiro, Professor of Medical Diagnosis in Helena Pavlona Clinical Institute, St. Petersburg.—Dr. Augusto da Rocha, Professor of Clinical Medicine in the University of Coimbra, Portugal.—Dr. Leopold Weiss, Professor of Ophthalmology in Heidelberg.—Dr. Theodor Husemann, Professor of Pharmacology in the University of Göttingen, at the age of 67 years. He was a voluminous contributor to medical literature.—Dr. Julius Homann of Hamburg, one of the Assistants in the Kiel Hygiene Institute, has died from enteric fever which he contracted while engaged in the study of pure cultures of virulent typhoid bacilli.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In February the following candidates passed in the subjects indicated:—

Surgery.—G. Aldridge, London Hospital; E. A. Dunn (Section I.), Royal Free Hospital; J. C. Furness, Glasgow and Charing-cross; B. Goitein (Section I.), Vienna; H. B. Hanson (Sections I. and II.), Royal Free Hospital; H. A. Higgens (Section II.), Guy's Hospital; H. Jessop (Section II.), Birmingham; R. A. Jones (Section I.), St. Mary's Hospital; S. Page (Section II.), Birmingham; J. Ward (Sections I. and II.), Sheffield; and G. H. Watson, St. Bartholomew's Hospital.

Medicine.—C. E. C. Child (Sections I. and II.), Charing-cross Hospital; H. E. Darlington, Birmingham; M. E. Fendick (Sections I. and II.), Royal Free Hospital; G. J. W. Keigwin (Section I.), London Hospital; G. R. Lucas, Edinburgh and Charing-cross Hospital; F. McTavish (Sections I. and II.), Toronto; S. Page (Section II.), Birmingham; E. R. Risien (Section II.), St. Bartholomew's Hospital; and P. Southan (Sections I. and II.), Birmingham.

Forensic Medicine.—C. E. C. Child, Charing-cross Hospital; H. E. Darlington, Birmingham; E. N. de V. Dawson, St. Thomas's Hospital; G. J. W. Keigwin, London Hospital; F. McTavish, Toronto; S. R. Thomas, Guy's Hospital; and M. J. Williams, St. Bartholomew's Hospital.

Midwifery.—C. H. Brookes, Durham and St. George's Hospital; A. E. U. Hawkes, Liverpool; W. J. Hogg, Belfast; H. Howells, St. Thomas's Hospital; J. Kemp, Manchester; J. C. McCarroll, Belfast; D. Morrow, Middlesex Hospital; E. C. Pratt, Birmingham; J. Ward, Sheffield; C. Watson, Dublin and Westminster Hospital; and E. Yoxall, Birmingham.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—C. H. Brookes, M. E. Fendick, J. C. Furness, H. B. Hanson, A. E. U. Hawkes, S. Page, and G. H. Watson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Bolognini has been recognised as *privat-docent* of Pædiatry and Dr. Fochessati as *privat-docent* of Orthopædics.—*Copenhagen:* Dr. J. Fibiger has been appointed to the chair of Pathological Anatomy in succession to the late Professor Lange.—*Cracow:* The gynæcological clinic, under Professor Jordan, has had to be closed for the purpose of thorough disinfection, no less than five cases of septicæmia having occurred within a fortnight.—*Giessen:* Dr. Dannemann has been recognised as *privat-docent*.—*Göttingen:* Dr. A. von Hippel of Halle has been appointed to the chair of Ophthalmology.—*Gratz:* Dr. Adolf Jarisch, Extraordinary Professor of Dermatology, has been promoted to the Ordinary Professorship of this subject.—*Greifswald:* Dr. Alexander Westphal, a son of the late well-known neurologist of Berlin, has been appointed Extraordinary Professor of Psychiatry and Neurology.—*Halle:* Dr. H Schmidt-Rimpler of Göttingen has been appointed to the chair of Ophthalmology.—*Heidelberg:* Dr. Franz Nissl and Dr. Georg Marwedel have been promoted to Extraordinary Professorships. Dr. Braus of Würzburg has been offered an Extraordinary Professorship of Comparative Anatomy.—*Kieff:* Dr. A. Muratoff, Professor in the University of Iurieff (Dorpat), has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. Rein.—*Lemberg:* Dr. Adam Solowij has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Moscow:* Dr. Minakow has been appointed Extraordinary Professor of Forensic Medicine.—*Pavia:* Dr. Costanzo Zenoni of Turin has been recognised as *privat-docent* of Pathological Anatomy.—*Tokio:* Professor Beneke, Prosector in the Brunswick Hospital, has been offered a Professorship.—*Vienna:* Dr. Arthur Katz has been recognised as *privat-docent* of Internal Medicine.

THE LATE PROFESSOR A. HUGHES.—At the meeting of the court of governors of the University College of South Wales and Monmouthshire held on Feb. 20th, Dr. W. T. Edwards stated that £800 had been received towards the £1000 required for the museum of anatomy proposed as a memorial to the late Professor A. Hughes.

BRISTOL HOSPITAL SUNDAY FUND.—At a meeting of the council of this fund, held on Feb. 20th under the presidency of the Lord Mayor, the honorary treasurer reported that he had received £1619 from 215 collections, and that there were still the results of 25 collections to come in. Last year the fund realised £1314. The council decided to distribute £1500 amongst the various Bristol medical charities.

PRESENTATION TO A MEDICAL MAN. — On Feb. 9th, at a numerously attended social meeting in the Tweeddale-street Board School, Rochdale, under the auspices of the St. John Ambulance Corps, Mr. Richard B. Sellers, M.R.C.S. Eng., L.R.C.P. Edin., was presented by the corps with a pair of silver flower vases, as a token of appreciation for his instructive lectures to the members of the ambulance classes.

CHILD INSURANCE.—The grand jury at the Bristol Assizes on Feb. 21st found true bills against an insurance clerk and his wife who are charged with attempting to murder the man's young son. The child was insured, and the grand jury submitted a presentment recording their opinion that the abuse of child insurance should be inquired into and dealt with by Parliament. Mr. Justice Darling promised to forward this to the Home Secretary and said that no doubt it would receive attention.

AN INTERNATIONAL CONGRESS OF NURSES. — There is to be an International Congress of Nurses in Buffalo, U.S.A., next September, during the time of the Pan-American Exposition. We are informed that the Congress meets with the intention to celebrate the new century and to cement and strengthen the national and international organisations which the nurses of America, Great Britain, the English colonies, Denmark, and Holland have for the last few years been intent upon developing.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College: Mr. E. A. Chartres, Mr. Patrick I. Dempsey, Mr. A. Fullerton, Mr. J. J. Harding, Mr. P. K. Joyce, Mr. G. M. Keating, Mr. R. J. D. Kenny, Mr. J. M. Morrissey, Mr. J. O'Donoghue, Mr. R. H. Oliver, Mr. C. J. Powell, Mr. T. O'C. Redmond, Mr. T. N. Smith, Mr. E. F. Stephenson, Mr. E. W. Stoker, Mr. F. Warren, and Mr. T. Wilson.

PATRICROFT WORKHOUSE HOSPITAL. The new infirmary of the Barton-upon-Irwell Union Workhouse was recently opened. The estimate for the work so far completed—i.e., the infirmary itself—was £18,900, but the entire scheme, which includes nurses' home, &c., will cost £30,000. It is on the pavilion principle, extending to right and left from the central offices which are connected by a corridor to the workhouse itself. Dr. J. M. Rhodes was present and in the course of the proceedings said he thought "they hardly appreciated as they should the enormous progress that had been made in regard to poor-law administration since the accession of the Queen." When the Act of 1834 was passed £1 15*s.* of the income of every man in the country was paid annually for the relief of the poor. "To-day they had a splendid institution and yet the cost per head was only the odd 15*s.*" But more important still, there was no longer the same grinding down of the poor and never was so much consideration shown to them as at the present time. At the beginning of the Queen's reign "the paupers were put five and six in a bed and even fever patients two or three together. The imbeciles herded together on heaps of straw." It does not seem probable that we shall ever fall back to such a condition of barbarism.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Army Medical Service.

IN the House of Lords on Thursday, Feb. 21st, the Earl of KILMOREY and Earl SPENCER invited from the Government a statement of their intentions with regard to the recommendation of the South African Hospitals Commission of an expert inquiry into the steps required for the improvement of the Army Medical Service. In response to this invitation both Lord RAGLAN, Under Secretary of State for War, and the Marquis of LANSDOWNE, the late head of the War Office and present Secretary of State for Foreign Affairs, spoke. The latter said that it was the intention of Mr. Brodrick to have recourse to the best expert advice that he could obtain, whether in the medical profession or elsewhere, but whether it was to be taken by the appointment of a committee or a commission, and whether the inquiry should or should not be departmental, were matters for which Mr. Brodrick desired time for further consideration.

Medical Act (1858) Extension Bill.

General LAURIE has introduced again in the House of Commons his Bill for the extension of the Medical Act of 1858. In a memorandum attached to the measure he says that since the passing of the Medical Act very great advance has been made in medical education throughout the empire, and especially in the self-governing colonies, and the Bill provides "that where the examinations and course of education at the principal colonial schools of medicine are in all respects the same as those practised in the United Kingdom, and subject to the supervision of the General Medical Council, medical men from Greater Britain should, when proved to be properly qualified, be admissible to serve the empire in the naval and military and civil services of the Crown."

HOUSE OF COMMONS.

THURSDAY, FEB. 21ST.

Precautions against Small-pox.

Mr. JOHN CAMPBELL asked the President of the Local Government Board what steps were being taken to preserve London from the danger of an outbreak of small-pox epidemic so prevalent in Glasgow.—Mr. WALTER LONG replied: I am happy to say that according to the latest returns there is at present practically no small-pox in London. It is by the vaccination of unvaccinated persons and the revaccination of adults that effective steps can best be taken to prevent an outbreak of this disease.—The recital of the second part of this answer was received with loud cheers of commendation.

FRIDAY, FEB. 22ND.

South African Hospitals Commission.

Mr. BRODRICK, in the course of a reply to a question, gave an assurance that any case in which a witness before the South African Hospitals Commission might be proved to have been prejudiced in any way by his giving evidence would be dealt with by the War Office in an exemplary manner.

MONDAY, FEB. 25TH.

The Small-pox Epidemic in Glasgow.

The LORD ADVOCATE, in reply to a question, said that he was informed by the Local Government Board that during the period from April 7th, 1900, to Feb. 21st, 1901, 1086 cases and 122 deaths from small-pox were reported in Glasgow.—Mr. O'DOHERTY asked the Chief Secretary to the Lord Lieutenant of Ireland (1) if his attention had been directed to a case of small-pox near Cardonagh, county Donegal, imported into that district by a man lately arrived from Glasgow, and what steps (if any) the Local Government Board for Ireland would take to prevent any more such cases being imported from Glasgow; (2) whether he was aware that the request made by the public health committee of the Londonderry Corporation to the Local Government Board to issue a sealed order preventing the importation of old clothes and rags into that city and district from Glasgow during the prevalence of the small-pox epidemic in the latter city had been refused; and (3) whether, considering the intimate touch of Londonderry and district with Glasgow, the Local Government Board would direct the Londonderry port sanitary authority to take precautions with respect to the examination of the cross-Channel steamers similar to those taken by them during the late bubonic plague epidemic in Glasgow.—Mr. WYNDHAM replied: The medical inspector of the Local Government Board, who has made careful inquiry into the allegation contained in the first paragraph, states that it is absolutely without foundation. The Board were unable to comply with the request made by the public health committee, as it has not been shown that small-pox is conveyed through the medium of old clothes. The Board do not consider it necessary to enforce in respect of small-pox the precautionary measures which were held to be essential in respect of bubonic plague. The Board have informed the authorities at Londonderry and other ports that vaccination and revaccination provide the best safeguards against a spread of small-pox.

Vaccination in Leicester and Gloucester.

Mr. COGHILL asked the President of the Local Government Board whether vaccination was now being generally practised in the towns of Leicester and Gloucester; whether he could state the number of unvaccinated persons in each town and of persons who had received certificates of exemption as conscientious objectors; and what steps the Local Government Board were taking to secure the due enforcement of the law with regard to vaccination.—Mr. WALTER LONG replied: The reply to the first part of the question is in the negative. I cannot state the number of unvaccinated persons in Leicester and Gloucester, but from the latest returns it appears that in Leicester of the children born during the 18 months ended June 30th last 388 have been vaccinated, while certificates of conscientious objection have been obtained in respect of 534. The corresponding figures as regards Gloucester are 879 and 395. Medical inspectors of the Local Government Board visited both towns last year in connexion with the performance of vaccination. As, however, the latest returns are not satisfactory I have decided that further visits shall be paid by inspectors as early as possible with a view of ascertaining in what manner the duties of the vaccination officers are now being carried out.

The Examination of Imported Food.

Mr. O'MARA asked the President of the Board of Agriculture if he

could state how many samples of consignments of imported food had been taken for analysis by the Commissioners of Customs (under the Sale of Food and Drugs Act, 1899) during the year 1900, how many such samples had been found adulterated, and what was the nature of such adulterations; and whether any prosecutions had resulted.—Mr. AUSTEN CHAMBERLAIN (on behalf of Mr. Hanbury) replied: The number of samples analysed was 1590, of which 26 were reported against. In seven cases fines were recovered. In the remaining 19 the circumstances were not such as, in the opinion of the Commissioners of Customs, would have warranted prosecution. Legal proceedings are now pending in four cases which have occurred since the beginning of the present year.

TUESDAY, FEB. 26TH.

Inoculation for Typhoid Fever.

Sir WALTER FOSTER asked the Secretary of State for War if he was aware that Professor Wright of Netley had stated, as the results of inoculation for enteric fever in one regiment, that the incidence of the inoculated was 0·55 and the death-rate 0·27 per cent., while in the uninoculated it was 6·14 and 3·35 per cent. respectively; and whether he could inform the House of the results of inoculation for typhoid fever or enteric fever among the forces serving in South Africa.—Lord STANLEY (on behalf of Mr. Brodrick) replied: The statement of Professor Wright referred to the official statistics from India for the 15th Hussars. There are no statistics available for the forces in South Africa. It will not, I fear, be possible to go into them properly until the war is over. The pressure on our medical officers for returns of various descriptions is a heavy addition to their pressing duties.

ROYAL COMMISSION ON ARSENICAL POISONING.

THE Arsenical Poisoning Commission met for the first time for the examination of witnesses on Friday, Feb 22nd, in one of the rooms of the Westminster Palace Hotel. All the members of the Commission were present—namely: Lord Kelvin (chairman), Sir William Hart Dyke, M.P., Sir W. S. Church, Professor Thorpe, Dr. B. A. Whitelegge, and Mr. H. Cosmo Bonsor, with Dr. G. S. Buchanan, secretary to the Commission. The Commission is appointed to ascertain with respect to England and Wales the amount of recent exceptional sickness and death attributable to poisoning by arsenic, whether such exceptional sickness and death have been due to arsenic in beer or in other articles of food or drink, and if so, to what extent, by what ingredients, or in what manner the arsenic was conveyed, and in what way any such ingredients became arsenicated; and if it is found that exceptional sickness and death have been due to arsenic in beer or in other articles of food or drink, by what safeguards the introduction of arsenic therein can be prevented.

THE EVIDENCE OF DR. TATTERSALL.

Dr. C. H. TATTERSALL, medical officer of health of the borough of Salford, was the first witness examined, and in reply to the CHAIRMAN he said that he had made special inquiries into the recent epidemic of arsenical poisoning attributed to beer and had prepared a special report on the subject for presentation to the Salford Town Council, the report applying only to the epidemic in the town. This report he offered to the Commission. From the accompanying charts it would be seen at once that there was a great rise in the number of deaths from alcoholism, peripheral neuritis, or multiple neuritis, in the month of June, 1900, and that this continued to increase, reaching its maximum in the month of November. On Nov. 9th Mr. R. D. Cran, Poor-law medical officer of the Regent-road district, called and informed him that he had a very large number of patients suffering from what appeared to be alcoholic peripheral neuritis. His diagnosis had been confirmed by finding that all the sufferers took beer, but he had been surprised to learn that many of the patients had not been excessive drinkers. He obtained samples of beer from public-houses supplied by 14 different breweries, sent them for analysis, and proceeded to make inquiries into the cases of which Mr. Cran had given him a list. It was soon ascertained that the sufferers were all beer-drinkers and several of them were employees of a local brewery. The amount of beer consumed varied very much—viz., from a pint to 16 pints per day. Witness then explained that the preliminary examination of the beer by Professor Delépine was in progress when on Nov. 20th they heard of the discovery by Dr. E. S. Reynolds of arsenic, and this observation was at once confirmed. It had been impossible to obtain anything approaching accurate information as to the extent of the disease. For obvious reasons the public generally had been very reticent and expected the medical attendants to be the same. Almost all the cases returned to him were among the poorer classes of the population, but they were not alone the sufferers. He knew instances where people in the better condition of life had suffered in exactly the same way, though those instances had not been brought officially to his notice. There could be no doubt that a very great number, probably some thousands, had suffered to a greater or less extent in Salford. The number of cases reported was 996, of which 281 were males, 349 females, and 366 sex not stated. One medical practitioner informed him that in August and September he had a great number of cases of herpes zoster and witness knew of several instances where persons who were in the habit of drinking some of the incriminated beer, in strict moderation, found in June, July, and August that the beer caused disturbance of the digestive functions, such as vomiting and diarrhœa, and they ceased to take it. So far as he had been able to ascertain there was a marked falling off in the amount of beer consumed in the district about the end of September, two months before the discovery of the poison, showing that many persons must have been affected in a similar way. In 150 cases the source of the beer was carefully traced and it was found that in every instance where one brewery could be connected with the poisoning, that brewery was using Bostock's sugar. The deaths resulting from the special amount of arsenic contained in Bostock's brewing sugars from May to November could only be ascertained by comparing the deaths from chronic alcoholism, peripheral neuritis, or alcoholic neuritis in the period from June, 1900, to January, 1901, with those from the same causes in previous years, and taking in addition the deaths registered as due to cirrhosis of the liver treated in the same way. Thus from June 1st, 1900, to January 1st, 1901, there were registered from peripheral neuritis 47 deaths, from alcoholic neuritis 10, from multiple neuritis two, and from chronic alcoholism 32 deaths, or a total of 91 deaths in the eight months as compared with seven, the average number for the same period in the preceding five years. This left a total of 84 deaths which might be considered to be due to the poisoning, in addition to those which were certified as cirrhosis of the liver. In the year 1900 there were 52 deaths registered as due to cirrhosis of the liver, as compared with 30, the average for the preceding five years, which left an additional 22 deaths as in all probability due to the poisoning, especially considering that the post-mortem examination of the victims showed that even where large amounts of alcohol had not been taken the liver was greatly hypertrophied. There was one death registered from Addison's disease and he had good reason to believe that this was due to the arsenical poisoning. This made a grand total of 107 deaths in Salford up to the end of January, 1901, probably due to arsenical poisoning from beer, and there could be no doubt that many of the persons still suffering from the effects of the poison would succumb in the near future. He had tabulated the results of replies received from medical practitioners respecting the symptoms of 296 cases. This brought out—running of eye and nose, 106; pigmentation, 68; skin affections, 107; sensory disturbances, 234; motor disturbances, 228; gastro-intestinal troubles, 39; anasarca, 10; and mental disturbances, 9. The mortality figures showed that women were much more liable to succumb to the effects of the poison than men. Thus, out of 115 deaths 28 were males and 87 were females. It was impossible to say whether this was due to the females taking more of the poison or whether their powers of resistance were less. Probably it was a combination of the two reasons. As to age, the greatest number of cases were amongst persons from 40 to 50 years of age. For obvious reasons it was exceedingly difficult to obtain anything approaching accurate information as to the amount of beer consumed by any individual and there was a strong tendency to minimise the quantity in most instances. The information in the following table, which represented the analysis of 150 cases, had been carefully sifted and made as accurate as possible:—

Small amount, not exceeding one quart daily	53
Medium amount, not exceeding half a gallon daily	44
Large drinkers, exceeding half a gallon daily	53
	150

Assuming that the beer contained on the average one quarter of a grain per gallon, which was, he thought, a fair assumption, the amount of arsenic taken in a week by one of the class of small drinkers would be about half a grain, and considering that one-twentieth of a grain of arsenic would be a dangerous quantity to take daily for an unlimited period it was easy to understand that susceptible persons might be poisoned. The second class would take about one grain per week and the third from two to four grains per week. Witness then explained in detail the precautions taken to prevent the epidemic spreading, and afterwards the processes adopted in brewing beer and in the manufacture of sulphuric acid. In the latter connexion he said that the purest acid was made from native Sicilian brimstone. This alone should be used whenever the ultimate destination of the manufactured product was human consumption. Witness then gave his conclusions. He said it might be considered proved by the clinical symptoms, the presence of arsenic in the urine of patients and in the body of patients who died, that the cause of this outbreak of epidemic disease was poisoning by arsenic. If the beer had been brewed from malt and hops alone no serious damage from poisoning with arsenic could have occurred, although malt more or less impure might have been used by the brewer, and in the light of the results of this investigation it might be considered that there was no reason why beer brewed from malt and hops should under any circumstances contain more than one two-hundredth part of a grain per gallon, as the use of anthracite fuel in the preparation of malt and subsequent brushing and polishing gave a practically pure article. Again, it was quite clear that glucose and invert sugar as usually prepared were absolutely innocuous substances, and considering the fact that chemical science was progressing so rapidly in the direction of replacing natural products with manufactured articles it would appear unreasonable to forbid the use of these substances provided that some means could be devised by which carelessness of one or more individuals could be prevented from endangering the lives and health of the public. At the same time it should be recognised that any person replacing a natural substance by a manufactured article in the preparation of any food stuffs took upon himself the responsibility of seeing that no injury should ever result from such substitution. He would suggest that chemical manufacturers be compelled by law to label every article whether apparently meant for use in the preparation of food stuffs or not which contained any known poison, with a statement that such poison, naming it, was present. The Food and Drugs Act should also be amended so as to make the contamination of food stuffs with poisonous matter in appreciable quantity, whether to a dangerous extent or not, and whether to the knowledge of the seller or not, an offence within the meaning of the Act. The seller could always and ought always to protect himself by obtaining a warranty from the person from whom he obtained the substance. This investigation had shown the great importance of some improvement being made in the arrangements for the notification to the health authorities of outbreaks of disease. Certain specified infectious diseases were notified under the Infectious Diseases Notification Act, but it should be recognised by the medical profession that the public had provided an organisation for the express purpose of dealing with outbreaks of disease, and notification of any disease of an unusual character should take place as a matter of course. Immediately after the beginning of December he sent out forms to every medical practitioner in Salford asking for particulars of cases and he received lists from a large number. He sent out forms again in January asking for any further cases, the

result being that in January he heard of 39 cases which were not included in the original list. These 39 cases were all inquired into and in every instance the illness was found to have commenced and the symptoms to have been clearly marked before Dec. 1st. He had not found any cases of illness resulting from confectionery, or jams, or syrups. Samples of these substances had been analysed but with entirely negative results. It was stated in evidence more than once in the inquiries before the coroner that Bostock's invert sugar and glucose were supplied only to brewers and witness obtained this information when he visited Bostock's works.

By Sir WILLIAM HART DYKE: He could not indicate what proportion of cases had escaped notice. The problem was one on which he had thought a good deal, but he could see no way of getting at any information that would be of value. The strongest indication that there had been a great amount of illness beyond what was known to the health authorities was the great falling-off in beer-drinking; people gave up beer and took to whisky. When this inquiry began the possibility of the presence of arsenic in beer never occurred to him.

By Mr. COSMO BONSOR: It was lead he first thought of, and these beers were analysed for it, but he satisfied himself that the cases were not of lead-poisoning.

By Professor THORPE: It was generally considered that spirit-drinking was the cause of peripheral neuritis, but in these inquiries in Manchester they found that, although whisky might be a cause, beer was a commoner cause than had generally been supposed. In his opinion this epidemic was clearly due to the use of a particular sugar in the making of beer and to that extent was an accidental occurrence. He had, of course, approached the subject purely from the public health standpoint. A number of people were ill. He inquired into all their circumstances and he found one thing in common—they all drank beer. Samples of beer obtained in the ordinary way were found to contain arsenic. Arsenic accounted for the symptoms and he was satisfied without going any further.

By Dr. WHITELEGGE: One of the lessons of this epidemic was that arsenic was more of a cumulative poison than had been supposed. He felt certain that if a return of these cases had been sent to the public officers of health they would have noticed what perhaps one medical man might not have noticed—namely, the increase in peripheral neuritis—and there would have been inquiry. The ideal condition would be a universal notification of disease—all disease—but failing that he thought that it should be generally understood by the medical profession that there was a machinery already provided for inquiry into the causes of death, and when unusual sickness—unusual either in type or amount—existed it should be reasonably expected that a medical practitioner should communicate with the public health authorities.

THE EVIDENCE OF DR. REYNOLDS.

Dr. ERNEST S. REYNOLDS, assistant physician to the Manchester Royal Infirmary and visiting medical officer to the Manchester Workhouse Infirmary, was then examined, and in answer to the CHAIRMAN he said that in this condition, which had been called for many years "alcoholic paralysis," there were certain sensory disturbances quickly followed by certain motor disturbances, certain heart symptoms not infrequently, and also not infrequently certain quite peculiar mental symptoms. The sensory symptoms consisted principally of prickings and burnings in the hands and feet, cramps in the calves, and they were associated also with a very exquisite tenderness found with pressing or squeezing the muscular masses between the fingers. This tenderness was found in very few other conditions. As regards the motor symptoms these consisted of gradual loss of power in the feet and hands, the loss of power being due largely to an inflammation of the nerve trunks in the limbs or peripheral neuritis. This loss of power was so peculiar that a particular form of gait was produced. The hands became paralysed and drooping and in the advanced cases the diaphragm became paralysed so that there was very great difficulty in breathing. The mental symptoms consisted in a very characteristic loss of memory of time and place, so that a patient could not tell how long he had been in the ward. Many of the patients were quite incapable of telling where they were. Those were the symptoms the medical profession had known for many years and such cases were very common in Manchester—so common that in the years 1887 to 1899 at the Manchester Royal Infirmary, where they had 1500 medical cases admitted each year, the average number of cases of alcoholic paralysis was 20 annually. As far as he could hear these cases were more common in Manchester than, say, in Scotland or in London. In chronic arsenical poisoning they got, as a rule, first of all, digestive disturbances, vomiting, and diarrhœa. They next got symptoms of cold in the head, running of the eyes, running of the nose, and bronchial headache. They also got in not a few cases peculiar acute rashes on the body. They then got marked sensory disturbances exactly like those of alcoholic paralysis and also motor disturbances exactly the same as those he had described. He had seen a considerable number of arsenical cases and thinking over them he could not differentiate between the sensory and motor symptoms of the present epidemic and those which he had seen previous to the epidemic in alcoholic paralysis. Later they got certain chronic skin affections marked by a peculiar pigmentation of the skin and a thickening of the palms of the hand and the soles of the feet. Comparing the symptoms of the so-called alcoholic paralysis with those of chronic arsenical poisoning one would say that the sensory and motor symptoms were practically the same, but that the skin symptoms were only found in the arsenical cases. To show that the sensory and motor symptoms were about the same this epidemic in Manchester had been going on for four months and many physicians in Manchester, gentlemen who were thoroughly well acquainted with the appearance of alcoholic paralysis, had been seeing these cases and none of them imagined that they were anything but cases of alcoholic paralysis.

Have you any reasons for doubting whether ordinary alcohol is or is not the cause of the so-called alcoholic paralysis?—It is a very difficult question, and I wish to put my views forward with great diffidence, but there are several points which make me think that ethylic alcohol is not the cause of neuritis.

Dr. REYNOLDS then proceeded to explain his views in detail. For many years it was stated that alcoholic neuritis only occurred in spirit-drinkers. The first case of alcoholic neuritis that he ever saw was in 1885 and that occurred in a gentleman who drank absolutely nothing but beer. Since then he had seen many hundreds of cases of alcoholic neuritis and the sufferers had invariably taken beer either alone or with spirits. On the contrary, he had seen many cases in private and hospital work where the people had taken nothing but spirits and never had he seen a pure spirit-drinker with alcoholic neuritis. He had seen a gentleman who took a bottle of whisky per day and a lady who took a bottle and a half per day. He had at various times inquired of Scotch physicians and had learned from them that in a country where much whisky was consumed there was very little neuritis. Some weeks ago he sent to Aberdeen, Glasgow, Edinburgh, and Dundee, and also to Belfast, and obtained corroboration of his opinion that in this matter it was not alcohol *per se*. Witness then read a long letter from Sir William Gairdner commenting on the rare and exceptional character of the disease in Scotland and suggesting that alcohol though associated with it was not the leading factor in its etiology. Continuing, witness said that although he had not seen neuritis in a pure spirit-drinker, he had no doubt that it had occurred, but in the Manchester district it was infinitely more common among beer-drinkers. Dr. Reynolds having explained what led him to suspect beer as the cause of the mischief and the results of the analyses made, said that the symptoms of the present epidemic agreed absolutely with those of an epidemic which occurred in Paris in 1828 and which was called "acrodynia." In that case nobody thought of its being arsenical. An epidemic occurred in 1888 in Hyères which was undoubtedly arsenical and was due to arsenic having been put into wine instead of gypsum, the pigmentation giving the key to the cause. He had not the slightest doubt that the Paris epidemic was arsenical, for the symptoms described were identical with those he had found in Manchester and had set out in an article in THE LANCET of Jan. 19th, 1901, p. 166, when he had not read the account of the Paris epidemic. Giving the chronological order of the symptoms in Manchester, witness said that digestive symptoms had started first; in perhaps 50 per cent. of the cases they were either vomiting or diarrhœa. The next symptoms were cold in the head and irritation of the larynx and the bronchia. Then came the rash lesions, next the sensory disturbances, the burning of the hands and feet, and then in about three or four days the patients complained of the loss of power, especially in the feet and also partly in the hands. There was difficulty about the classification of cases, due largely to the peculiar idiosyncrasy which people seemed to have as regards arsenic. For instance, a wife in a family died from the disease and at the inquest the husband said that he took quite as much beer of the same kind as his wife and was perhaps well or hardly suffering. One group of cases presented practically all the symptoms, whilst another only presented the symptoms of heart or liver affection—that was to say, they were breathless and had swollen feet, and very few had sensory disturbances. Other cases, again, had the principal sensory disturbances and nothing much else. Others had sensory and motor disturbances, and it was these that looked exactly like an old case of alcoholic paralysis. In these cases a careful examination of the soles of the feet not infrequently revealed scales there, so that it seemed to him very probable that many of the cases which they had been calling alcoholic paralysis they would have found to be arsenical if they had only known the symptoms to look for. It seemed to him possible that quite small quantities of arsenic taken for considerable periods might by accumulating in the system set up a paralysis without any of the other symptoms. Since the beginning of October he had seen in the Crumpsall Workhouse Infirmary 403 cases, 237 males and 166 females, and in November and December in the Royal Infirmary he had seen 170 cases, 110 males and 60 females. Altogether he had seen about 650 cases. These figures showed more males than females, but many women when the symptoms became known were shy about coming to the hospital, and, indeed, did not come unless they were very seriously ill.

By Sir WILLIAM CHURCH: His opinion that alcoholic neuritis was more common in Manchester than in London was based on conversations with London physicians.

By Dr. WHITELEGGE: He was of opinion that alcohol predisposed people to arsenical poisoning.

The Commission then adjourned for a week.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BENNETT, J. H., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Staplehurst District of Kent.

BYERS, JOHN W., Professor, M.D., M.A.O., has been appointed Examiner in Obstetric Medicine and Gynæcology in the Royal University of Ireland.

DEY, ALEXR., M.B., C.M. Aberd., has been appointed Certifying Surgeon under the Factory Acts for the Woolér District of Northumberland.

ELLIS, C. J., M.B., C.M. Aberd., has been appointed Medical Officer and Public Vaccinator for the No. 3 Sanitary District of Battersea, Wandsworth Union.

FLITCROFT, T. E., L.R.C.P. Edin., L.F.P.S.G., has been appointed Honorary Surgeon to the Bolton Infirmary, vice William Gillibrand, resigned.

GOLDSMITH, GEORGE POCOCK, M.D. Durh., M.R.C.S. and L.S.A., has been appointed Consulting Physician to the Bedford County Hospital.

JENKINS, C, C., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Assistant Medical Officer for the Workhouse at Cardiff.

KINGSFORD, B. H., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Woking Sanitary District, Guildford Union.

LAWSON, T. C., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Sherston District of Wilts.

LINDSAY, J. A., Professor, M.D., M.R.C.P. Lond., has been appointed Examiner in Medicine in the Royal University of Ireland.

MOYNAN, RICHAND M., M.D., M.Ch. R.U.I., has been appointed Medical Officer for the Borough of Cowbridge, Glamorganshire, vice A. W. Shepherd, deceased.

MYLES, GEORGE, L.R.C.P., L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Limerick District.

PEACOCK, W. E., M.D. Durh., B.S., has been appointed Certifying Surgeon under the Factory Acts for the Nuneaton District of Warwickshire.

PHILLIPS, F. B. WILLMER, M A., M.D. Oxon., B.Sc. Lond., M.R.C.S., has been appointed Physician to the Bedford County Hospital.

ROBB, A., M.B., C.M. Aberd., D.P.H., has been appointed Medical Officer of Health for the Paisley Town Council.

SHARPIN, EDWARD COLBY, L.R C.P. Edin. and L.M., M.R.C.S., has been appointed Consulting Surgeon to the Bedford County Hospital.

SMITH, H. H., L.R.C.P. Lond , M.R C.S., has been appointed Certifying Surgeon under the Factory Acts for the Uxbridge District of Middlesex.

SMITH, J. LORRAIN, M.D., has been appointed Examiner in Pathology in the Royal University of Ireland.

STACK E. C., L.R.C P., L.R.C.S. Irel., has been appointed Assistant Surgeon to the Burton-on-Trent Infirmary,

STAMP, W. D., L.R.C.P. Edin., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Plympton District of Devonshire.

STEELE, W. C., M.D. Brux., M.R.C.P. Edin., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Carshields District of Northumberland.

STONE, FREDERICK WILLIAM SMITH, L.R.C.P., L.R.C.S., L.M. Irel., has been re-appointed Medical Officer for the Kalston and North Stoke Districts by the Raynshaw Rural District Council.

THOMPSON, W. H., Professor, M.D., F.R.C.S. Eng., has been appointed Examiner in Physiology in the Royal University of Ireland.

WALKER, J. W. THOMSON, M.B., F.R.C.S., has been appointed Honorary Pathologist and Bacteriologist to the Paddington Green Children's Hospital, London, W.

WHITLA, W., Professor, M.D., has been appointed Examiner in Materia Medica in the Royal University of Ireland.

WILD, R. B., M.Sc Vict , B Sc., M.D. Lond., M.R.C.P., M.R.C.S., has been appointed Professor of Materia Medica and Therapeutics, Owens College. Manchester.

WILLAN, L. J., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Dorking District of Surrey.

WOOD, L. E., M.B. Lond., M.R.C.S., D.P.H., has been appointed Certifying Surgeon under the Factory Acts for the Penshurst District of Kent.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

BARNHILL POORHOUSE AND HOSPITAL, Springburn, Glasgow.—Male Junior Assistant Medical Officer. Salary £90 per annum, with board and apartments, &c.

BELGRAVE HOSPITAL FOR CHILDREN, Gloucester-street, S.W.—House Surgeon for six months. Gratuity £5, with board and lodging.

BOROUGH HOSPITAL, BIRKENHEAD.—Senior and also Junior Resident House Surgeon. Salary £100 and £80 respectively per annum, with board and washing.

CENTRAL LONDON SICK ASYLUM DISTRICT.—First and Second Assistant Medical Officers. Salary—First Officer, £100 per annum; Second Officer, £75 per annum; each with board and residence.

CHORLTON-UPON-MEDLOCK DISPENSARY. — Resident House Surgeon, unmarried. Salary £130 a year, with furnished rooms and attendance.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park. Physician to the out-patients.

CITY OF SHEFFIELD HOSPITALS FOR THE TREATMENT OF INFECTIOUS DISEASE.—Assistant Resident Medical Officer. Salary £150 per annum, with board, lodging, and attendance.

COUNTY OF LANARK: DISTRICTS OF THE LOWER AND MIDDLE WARDS.—Resident Physician for Lightburn Joint Hospital for Infectious Diseases, Shettleston, near Glasgow. Salary £130 per annum, with board, &c.

CROYDON UNION INFIRMARY, Mayday-road, Croydon. — Resident Assistant Medical Superintendent and Dispenser. Salary £120 per annum, increasing to £150, with furnished apartments, rations as per scale, and washing.

CUMBERLAND INFIRMARY, Carlisle.—Resident Medical Officer as House Physician during the first six months, and House Surgeon during the ensuing six months. Salary at the rate of £80 and £100 per annum respectively, with board, lodging, and washing.

DOVER HOSPITAL.—House Surgeon, unmarried. Salary £100 a year, with board, lodging, and washing.

GENERAL INFIRMARY, Gloucester, and GLOUCESTERSHIRE EYE INSTITUTION.—House Surgeoncy. Salary £100 per annum, with board, residence, and washing. Also Assistant House Surgeon for six months. Salary at the rate of £30 per annum, with board, residence, and washing.

HOSPITAL FOR WOMEN AND CHILDREN, Leeds.—House Surgeon for six months, eligible for renewal. Non-resident. Salary at the rate of £125 per annum.

LANARK COUNTY COUNCIL.—Assistant Medical Officer of Health. Salary £140 per annum, with travelling expenses.

LEEDS PUBLIC DISPENSARY.—Honorary Surgeon.

LIVERPOOL ROYAL INFIRMARY.—Honorary Physician.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £80 per annum, with board, residence, and washing.

LONDON HOSPITAL, Whitechapel, E.—Surgical Registrar. Salary £100 per annum.

LONDON HOSPITAL MEDICAL COLLEGE.—Assistant Demonstrator of Anatomy. Salary £90 a year.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon for six months. Salary at the rate of—House Physician and House Surgeon, £40 a year; Assistant House Physician and Assistant House Surgeon, £20 a year.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160 for the first year and £180 afterwards.

NORTHAMPTON GENERAL INFIRMARY.—Physician, not under twenty-five years of age.

NORTHERN NIGERIA, WEST AFRICA —Medical Officers. Salary £400 per annum and local allowance of 5s. a day during residence.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum, all found except board.

PARISH COUNCIL OF WESTRAY, Orkney.—Medical Officer and Public Vaccinator. Salary £90 per annum.

PRESTON ROYAL INFIRMARY.—Junior and Assistant House Surgeons. Salaries £80 and £60 per annum respectively, with board, lodging, and washing, &c.

ROYAL ALBERT HOSPITAL, Devonport.—Resident Medical Officer, unmarried. Salary £110 per annum, with board and lodging.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Resident Medical Officer, for six months. Salary at the rate of £120 per annum, with furnished apartments, board and washing.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Ventnor.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging in the hospital.

ROYAL SEA BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

SOUTHPORT INFIRMARY.—Resident Senior House Surgeon. Salary £80 per annum, all found.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London, E C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

STOKE-UPON-TRENT UNION.—Resident Medical Officer. Salary £200 per annum, with board, washing, and furnished apartments at the hospital.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies as Certifying Surgeons under the Factory Acts at Towyn in the County of Merioneth and at Ballylongford in the County of Kerry.

TORBAY HOSPITAL, Torbay.—House Surgeon. Salary £100 per annum and £5 for the nurses' lectures. Board, lodging, washing, &c.

TOWNSHIP OF MANCHESTER WORKHOUSE, Crumpsall.—Assistant Medical Officer. Salary £110 per annum, with furnished apartments, fire, light, washing, and attendance.

VICTORIA HOSPITAL FOR CONSUMPTION, Craigleith, Edinburgh.—Resident Physician, for six months. Residence, board, and a small honorarium to cover conveyance.

WARNEFORD HOSPITAL, Leamington.—House Surgeon. Salary £100 per annum, with board, washing, and apartments.

WARNEFORD ASYLUM, Oxford.—Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

DE JERSEY.—On Feb. 23rd, at Netherton, Guildford, the wife of Walter B. de Jersey, M.B. Cantab., of a son.

FINLAY.—On Feb. 19th, at Mary's-place, Raeburn-place, Edinburgh, the wife of Thomas Finlay, M.B, C.M. Edin., of a son.

GERVIS.—On Feb. 22nd, at Dyke-road, Brighton, the wife of Henry Gervis, M.A., M.B., of a son.

GORHAM.—On Feb. 21st, at Campbell House, Clapham-common, S.W., the wife of J. J. Gorham, M.D. Irel., D.P.H. Camb., J.P., of a daughter.

OLIVER.—On Feb. 22nd, at Westdene, Maidstone, the wife of Charles Pye Oliver, M.D. Lond., D.P.H., of a daughter.

UMNEY.—On Feb. 20th, at Crystal Palace-park-road, Sydenham, S.E., the wife of William F. Umney, M.D. Lond., of a son.

WILSON.—On Feb. 23rd, at Frederick-road, Edgbaston, Birmingham, the wife of H. Bagster Wilson, M.R.C.S., of a son.

DEATHS.

FLEMING.—On Feb. 25th, at 3, Woodside-terrace, Glasgow, William James Fleming, M.D., F.F.P. & S. Glasg., in his 53rd year.

NICOL.—On Feb. 20th, at Warwick House, Llandudno, James Nicol, M.D., J.P., and F.R.M.S., in his 86th year.

SINCLAIR.—On Feb. 18th, at Mount Pleasant, Liverpool, John Sinclair, M.D., aged 85.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ANDERSON v. COWARD: MEDICAL ETHICS IN NEW ZEALAND.

A LIBEL case was heard in the Supreme Court at Blenheim, New Zealand, on Dec. 5th and 6th, 1900, before His Honour Mr. Justice Edwards, which is not without medical interest. The plaintiff, Dr. William Anderson, sued the defendant, Mr. G. W. Coward, for alleged libel and slander, claiming £50 damages. To tell the story shortly, Coward had been treated in the Wairau Hospital to which Dr. Anderson is assistant surgeon. After his discharge from the hospital he had published statements casting a slur on the competency of Dr. Anderson. It was also alleged in evidence that Coward had said to sundry persons that he would have lost his leg if he had not changed his doctor. The defendant allowed that "to the best of his belief all he could have said to Mr. Healy was that he really thought he must have lost his leg if he had not gone to Dr. Redman." His Honour awarded plaintiff the full damages claimed with costs, and allowed seven guineas costs for the second day. Questions of medical etiquette were constantly discussed throughout the case, which depended for its medical interest mainly upon the many references to proper professional behaviour. Mr. W. E. Redman, who had treated Coward after Dr. Anderson, and to whom the defendant attributed his recovery, said in his evidence that on coming to Blenheim he had not intended to practise but only to do insurance work. On being asked to stop and to take the place of a practitioner who had recently left he consented and allowed a paragraph to be inserted in the local paper, having learned that such was the custom in New Zealand, setting forth his intention to practise. The paragraph also gave details of his career supplied by himself. About a week after the appearance of this paragraph in the paper he called upon the other medical men in the town—namely, Dr. Anderson and Mr. D. M. Nairn. They were both out and he left his card. It further came out in evidence that Dr. Anderson wrote on behalf of Mr. Nairn and himself saying that "they could not reciprocate" Mr. Redman's courtesy. One or two more letters passed, but Mr. Redman remained a stranger to his professional *confrères*. Undoubtedly this fact had something to do with the spirit in which the libel action was carried on. Had Dr. Anderson and Mr. Redman been friends we can hardly think that the action would have been brought. But we congratulate Dr. Anderson on having won the case. With regard to Mr. Redman's alleged breaches of medical ethics it must be remembered that, although the unwritten laws guiding the medical profession are applicable in spirit to medical men in every clime and of every nation, the details of medical etiquette vary in different localities. As regards a new practitioner calling on others the practice has in London almost dropped out. No metropolitan medical man would be considered by his colleagues in his locality to have committed a *lache* by not calling upon them when he arrived among them. It is a matter upon which he can please himself. Mr. Redman did call upon his brother practitioners, but he did not do so until his advertisement had appeared in the paper. As regards this advertisement a medical man again is, we believe, allowed in certain colonies by common consent to make a simple statement in the lay papers of his intention to practise. One medical man said in his evidence in the case under consideration that a recognised form existed running "Mr. —— has commenced practice at —— and may be consulted ——." But Mr. Redman allowed the insertion of a paragraph setting out details of his career in a way that seemed to be intended to encourage the laity to come to him. This he should not have done. The quack appeals to the public in advertisements to leave their medical men and come to the only real shop for cures; the slightest appearance of such an attitude is a contravention of the spirit of medical ethics.

WHO IS RESPONSIBLE?

M. D. writes as follows:—A engages B as locum-tenent during absence from home. B during this time orders for his own use, without the knowledge or consent of A, an instrument and drugs which when he leaves he takes away with him. Shortly after a bill is addressed to B at A's address and sent in several times. At last it is returned to the sender with "Address not known" written across it. Immediately it is returned to A, still made out in B's name, with a letter saying that the firm hold A responsible for the amount as B was doing a locum-tenent's work for A at the time that the goods were ordered. A is requested to settle the account. Is A responsible? The goods were not for use in his practice and he never saw or heard anything of them until the bill was sent to him. It makes the engaging of a locum-tenent rather a serious thing if he is allowed to run up bills for the principal to settle after his departure.

*** We shall be interested to hear if this position has ever arisen before. We cannot answer the question concerning A's responsibility, which is a purely legal one.—ED. L.

"A CASE OF AUTO-VACCINATION."

To the Editors of THE LANCET.

SIRS,—In the case of auto-vaccination described in THE LANCET of Feb. 23rd, p. 549, by Mr. G. H. Ormsby Mr. F. MacDougall is reported to have stated that he had never seen during his extensive experience as a "public vaccinator" a similar case.

Some years ago in my practice a woman, aged 64 years, nursing her grandchild, got inoculated through a scratch on her left forearm with the lymph from a broken vesicle on the baby's arm with the result that the vaccination went through its successive stages all right, and though this mature dame suffered considerable inconvenience and annoyance for the time being she seemed nothing the worse afterwards for her unwilling experience. I am, Sirs, yours faithfully,

Brighton, Feb. 25th, 1901. R. HILL SHAW, M.D. Dub.

DEAFNESS AND QUACKERY.

JUDGING by the advertisements which are continually appearing in newspapers and periodicals the unqualified people who undertake to cure deafness must find this business a very lucrative one. In many cases the shameless announcements take up columns or even entire pages in respectable journals and they must consequently cost a great deal of money, so it is clear that the revenue accruing through the publicity thus obtained must in the aggregate be enormous. As an example of the methods adopted by the self-styled "aural specialists" the following hard case may be cited. Mrs. A, a poor old woman who is very nearly stone deaf but contrives to eke out a precarious living by charing, being tempted by an advertisement in a local paper was induced to communicate with the advertiser, who by return of post sent her a formidable packet of papers, including a pamphlet entitled "Deafness and Noises in the Head, with Instructions how they may be Absolutely Cured," from which the subjoined extract is taken:—

> "I was now face to face with the fact that I was terribly deaf and that the specialists and scientists of the day were incapable of curing me. ..... Their mode of treatment was radically wrong. What I really required was a medicine which should reach the minute muscles of the inner ear, as upon their proper action the sense of hearing almost entirely depends, and I commenced experimenting to find out the exact combinations of medicines required to penetrate the 'middle' and 'inner ear' and to restore the little muscles (ossicles) to their natural state."

The parcel also contained a form in which ten or a dozen trivial questions were propounded. These Mrs. A. answered to the best of her ability and having returned the filled-in document she without delay received the following letter:—

> "—— House,
> "January —th, 19—.
>
> "DEAR MADAM,—I am in receipt of your favour of the —th inst. and after a careful diagnosis of your case am very pleased to be able to strongly recommend the system to you, fully believing that the result will be highly satisfactory. During my experience I have had several very similar cases to treat for in which I am pleased to say I was quite successful. Therefore I candidly advise you to send for the remedies enumerated upon the enclosed form, the use of which I feel sure would bring about a successful result in your case as in others of a like nature.
>
> "Awaiting the favour of your reply,
> "I am, dear Madam, yours faithfully,
> "——"

The "remedies" were thus described:

> "Pair of Drum Supports.
> Prep. No. 1 Lotion.
> Prep. No. 3 Powd.
>
> Cost, including Treatment and directions, &c., £1 7s. 6d."

Having with great difficulty scraped together this, from her point of view, enormous sum Mrs. A despatched it to ——— House, and in due course received the "remedies" which, it is hardly necessary to add, proved to be of no value whatever. The poor old woman's folly having come to the knowledge of a medical man in her neighbourhood he wrote to the "aural specialist" in the guise of a patient, detailing an impossible case of deafness, and in due course received duplicates of all the documents that had been sent to Mrs. A, including the above-quoted letter, the only difference being the substitution of "Sir" for "Madam." As, however, he failed to respond, in a few days a reminder reached him, and on his still keeping silence in a few days more he received an offer of the "remedies" for 15*s.* cash, the balance payable only on cure. This, too, he ignored, whereupon after another interval the "aural specialist" forwarded a final letter to say he was willing to send "the full treatment for the sum of 4*s.* 3*d.*, cash with order."

ARE THERE PINS WITH REMOVEABLE POINTS?

To the Editors of THE LANCET.

SIRS,—I do not know whether pins are made with points that can be readily broken off after insertion, leaving a smooth rounded stump that will not prick or catch easily in clothing. A pin of this description would be a boon to surgical dressers and nurses.

I am, Sirs, yours faithfully,

Feb. 25th, 1901. BANDAGE

KIMBALL'S ANTI-RHEUMATIC RING.

A CORRESPONDENT recently wrote to us asking whether we knew anything of Kimball's anti-rheumatic ring, also inclosing one of Kimball's circulars. We learn from perusing the circular that rheumatism is caused by acidity of the blood, that this acid crystallises, forming crystals presenting all the appearance of pounded glass, which irritate the nerves. We then learn that electricity is the only remedy but that it must be properly applied and this in the most gentle manner possible but continuously. Herein lies the marvellous power of Kimball's anti-rheumatic ring.

> "Worn during the twenty-four hours of the day, as soon as it comes in contact with the heat and moisture of the finger, a gentle current of Electricity, *of exactly the right strength*, is directed, which will at once quicken the circulation; *then the blood itself, coursing more quickly through the veins, will dissolve the crystals*, stop the pain, and give tone to the entire system. By its quickening the circulation the blood is enabled to throw off impurities. Thus we have Electricity in its most effective form, and thus is *Rheumatism* cured.
>
> "The ring is not charged with Electricity; nor does it contain any of the metals that enter into the construction of the many so-called electric-belts, pads, insoles, &c., &c. There is nothing about it to be lost by use. The metals of which the Ring is composed, in connection with the heat and moisture of the finger on which it is worn, and the acid which the Ring draws from the system as long as any remains, form a combination which generates a mild current of Electricity."

We thought it would be interesting to see one of these rings, so we sent for one and submitted it for analysis in THE LANCET Laboratory. Our consulting chemist reports that the specific gravity of the metal was exactly that of iron. It dissolved completely in hydrochloric acid with evolution of hydrogen gas. The solution yielded a quantity of ferric oxide on precipitation exactly equivalent to the amount of the metal taken for the experiment. The ring was non-magnetic. We have therefore no hesitation in saying that the statements contained in Kimball's pamphlet are mostly false. He talks about the "metals of which the ring is composed"; it is composed of only one metal—namely, iron, with a trace of carbon—and is no more capable of setting up a current of electricity than is a bunch of keys in the pocket. Its value is at the outside 2*d.*, and Mr. Kimball charges 10*s.* It is quite true that a number of persons seem to have persuaded themselves that the ring does good. For instance, the first testimonial runs as follows:—

> The Rev. CANON WILBERFORCE, 20, Dean's-yard, Westminster Abbey, writes:—"I have recommended your Anti-Rheumatic Rings to many. I can only say that up to date I have not had a twinge of *Rheumatism* since I first put on your Ring. It may be coincidence, but it is a fact, nevertheless."

None of the testimonials is of the least value from a scientific point of view. Many people even now believe that wearing an eelskin garter cures cramp, and a medical man has told us of an acquaintance of his who tried the anti-rheumatic ring but deriving no good from it took to carrying a new potato in his pocket with beneficent results. We do not see why the authorities should not prosecute Kimball for obtaining money under false pretences, for his ring is not composed of metals but of one metal, and it does not generate electricity when on the finger, while even if it were to, the electricity would not pass through the body but be short-circuited.

"THE CASE OF MR JOSEPH HENDERSON MARTIN."

To the Editors of THE LANCET.

SIRS,—I beg to acknowledge the two following subscriptions since my letter in THE LANCET of Feb. 23rd: M.R.C.S. Eng. (Bath), £2; Mr. J. F. Churchill (Chesham), £2 2*s.* Amount previously acknowledged in THE LANCET £48 5*s.*

I am, Sirs, yours faithfully,

Chester-le-street, Feb. 27th, 1901. H. LYON SMITH.

"MEDICAL SUPERSTITIONS."

To the Editors of THE LANCET.

SIRS,—An interesting chapter with regard to superstition is that relating to the examination of persons accused of sorcery or supposed to be possessed by a devil. Cicatrices, birth-marks, hysterical anæsthesia, dermographism, all had their significance. "M.B. Lond.," will find some interesting information and references in "Étude sur le Dermographisme ou Dermoneurose Toxivasomotrice," par Toussaint Barthélemy, Paris, 1893. I am, Sirs, yours faithfully,

X.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers tell me of any institution where the following case can be admitted by payment? A girl, aged six, of apparently weak intellect from birth, and epileptic, who has been cured of fits by trephining and now needs mental training and management. I am, Sirs, yours faithfully,

Feb. 25th, 1901. F.R.C.S.

Anxious.—1. The Schott treatment of heart-disease carried out at Nauheim. In certain cases the treatment has been successful, but no one should undergo it without having a medical opinion that he or she is likely to be benefited by it. 2. Cocaine can be used in certain cases as an anæsthetic, but it will not take the place of chloroform in big operations. The question is one which may well be put by our correspondent to her medical attendant.

Hilly Country would like to hear the views of gentlemen who have tried motor-cars for general practice. Will they replace the horse? What type is reliable for regular work and as a hill-climber? Is there any reliable car burning ordinary paraffin instead of petrol?

G. V.—It is not possible to exclude from district councils all who might possibly, and perhaps indirectly, benefit by the decisions of the councils. It is inadvisable that the medical officer should be both master and servant.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (9th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (4th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—9 P.M. Dr. J. Mitchell Bruce: Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. Lecture I.—Introduction. The Normal Heart at 40 and upwards. Influences that Threaten the Function and Structure of the Circulation at these ages. Strain. Alcohol. Tobacco. Free Living. Sedentary Habits. Uric Acid. Gout. Syphilis. Acute Febrile Processes. Nervous Influences. Bright's Disease. Emphysema. Complex causes. Family-Heart. Periodic Physiological Strain. Uterine Involution. The Grand Climacteric. Natural Dissolution of Advanced Life.

TUESDAY (5th).—PATHOLOGICAL SOCIETY OF LONDON (Jenner Institute of Preventive Medicine, Grosvenor-road, Chelsea).—8 P.M. Laboratory Meeting. Dr. G. Dean: Experiments on Immunity in Relation to the Pancreas and its Ferments.—Dr. A. Moore: The Immediate Diagnosis of Rabies.—Dr. Hédin and Mr. S. Rowland: On a Proteolytic Enzyme in the Spleen.—Dr. A. Harden: The Fermentation of Glucose by Sanarelli's Bacillus Icteroides.—Dr. R. T. Hewlett: (1) The Nature of the Indol Reacting Substance in Diphtheria Cultures; (2) The Identity of Achalme's Bacillus and the Bacillus Enteritidis Sporogenes (Klein).

THE BROWN ANIMAL SANATORY INSTITUTION (University of London, South Kensington, S.W.).—5 P.M. Dr. J. Rose Bradford (Professor-Superintendent): The Protozoa in their Relation to Disease, with especial reference to the so-called Tsetse-Fly Disease of South Africa.

WEDNESDAY (6th).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Dr. Boxall, Dr. Lea, and Dr. W. Duncan. Dr. Horrocks (President): Inaugural Address.

THURSDAY (7th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Dr. H. A. Caley: Some Clinical Features of Colitis.—Mr. J. Griffith: Gonorrhœal Iritis.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital).—4 P.M. Clinical Cases.

FRIDAY (8th).—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases will be shown by Sir Felix Semon, Dr. de Havilland Hall, Dr. J. Horne, Dr. Pegler, Mr. Lake, Mr. Waggett, and Mr. Robinson.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Discussion on the Recent Epidemic of Typhoid Fever among the Troops in South Africa (opened by Dr. H. H. Tooth).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (4th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Addison: The Topographical Anatomy of the Abdominal Viscera in Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. R. Crocker: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Edwards: Malignant Disease of the Rectum.

TUESDAY (5th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. J. F. J. Sykes: The Influence of the Dwelling upon Health. (Milroy Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. Burney Yeo: Consultation. (Medical.)

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Dr. A. Macfadyen: The Cell as the Unit of Life.

WEDNESDAY (6th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Addison: The Topographical Anatomy of the Abdominal Viscera in Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Prof. A. Carter: Clinical Lecture.

LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Dr. Stoker: Impaired Movements of the Vocal Cords. (Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Latham: The Stages of Pulmonary Tuberculosis.

THURSDAY (7th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. J. F. J. Sykes: The Influence of the Dwelling upon Health. (Milroy Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. Clinical Evening. Demonstration of Cases of Diseases of the Ear.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Dr. Still: Nervous Phenomena associated with Rickets.

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration: Dr. P. S. Abraham.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Saunders: Arsenical Neuritis.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. W. Hunter: Pathological Demonstration. (Post-Graduate Course.)

FRIDAY (8th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Addison: The Topographical Anatomy of the Abdominal Viscera in Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. StClair Thomson: Consultation. (Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. **It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.**

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

ON

PUBLIC HEALTH AND HOUSING:

THE INFLUENCE OF THE DWELLING UPON HEALTH IN RELATION TO THE CHANGING STYLE OF HABITATION.

Delivered before the Royal College of Physicians of London, on Feb. 28th and March 5th and 7th, 1901,

BY JOHN F. J. SYKES, M.D., D.Sc. EDIN.,

MEDICAL OFFICER OF HEALTH, ST. PANCRAS; LECTURER ON PUBLIC HEALTH, GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on March 5th, 1901.

TENEMENT HOUSES.

MR. PRESIDENT AND GENTLEMEN,—The only statistics available in reference to the old type of vertical houses sublet in separate dwellings or tenements are those derived from insanitary areas as a whole, and these areas embrace also some other types of houses. However, the inference to be drawn generally from these statistics is that these houses produce a very unfavourable influence upon health, especially amongst children, and conduce to the acquirement of infectious diseases and to the prevalence of phthisis and respiratory diseases.

UNDERGROUND DWELLINGS.

Underground dwellings are mostly found in tenement houses and it is to be regretted that there are no statistics available in reference to this class of dwellings. An investigation into their mortality and morbidity would be of considerable value. The only statistics that give some indication are from Berlin as quoted in the table below in reference to the mortality in the several stories of dwelling-houses. From this table it appears that in houses of six storeys and over the order of mortality from lowest to highest occurs on the first, second, ground, and third storeys, the basement, and the fourth floor.

TABLE I.—*Mortality in Berlin according to the Storeys in Dwelling Houses.*[2]

Storeys of dwelling-houses.	Of every 1000 of inmates died.		
	1875 to 1876.	1880 to 1881.	1885 to 1886.
Basement	35·6	23·6	21·1
Ground floor	29·4	21·8	20·4
First floor	28·6	20·6	18·4
Second floor	29·2	22·3	18·8
Third floor	32·9	22·0	19·0
Fourth and fifth floors ...	36·5	28·5	21·4

It is surmised that the domestic circumstances of those living in the basement are doubtless better than those of the inmates of the fourth and fifth floors, and that this accounts for the slightly lower mortality.

"FLAT" HOUSES.

An investigation into the statistics of Peabody Buildings in London was made by Dr. A. Newsholme[3] in 1888–90, and he came to the following conclusions:—1. In the year 1890, contrary to expectation, and notwithstanding the high birth-rate, the age distribution of the population of the Peabody Buildings was less favourable to a low mortality than that of London as a whole. 2. The death-rate of the Peabody Buildings averaged about two per 1000 lower than that of London during the 12 years ending with 1885. During the four subsequent years the death-rate of the Peabody Buildings has remained about stationary, while that of London has shown a further decline, thus making the metropolitan death-rate approximate more closely to that of the Peabody Buildings. 3. The death-rate at different groups of ages is lower in the Peabody Buildings than for the whole of London with the exception of the ages from 0 to 5 years and from 15 to 25 years. 4. The infantile mortality is much lower in the Peabody Buildings than for all London. During the nine years from 1882 to 1890 it averaged in London 151·9 per 1000 births and in the Peabody Buildings 139·2 per 1000 births. 5. The death-rate from diarrhœa is slightly lower and from enteric fever only half that of the whole metropolis. 6. On the other hand, the diseases more directly due to direct infection (scarlet fever, diphtheria, and still more, whooping-cough and measles) are more fatal, and therefore probably more prevalent. If the Metropolitan Asylums Board would admit cases of measles into their hospitals the mortality from measles might be very much reduced. 7. The death-rate from phthisis and other tuberculous diseases is slightly higher in the Peabody Buildings than for all London. 8. Farr's formula as to the increased mortality with increased density of population has no application to the Peabody Buildings. 9. The true density that should be considered is the number of persons to each room, not the number of persons to a given acre.

The medical officer of health of St. Giles, Mr. S. R. Lovett, has kindly supplied me with the records he has kept through a series of years of the population, births, and deaths in four large blocks of buildings in St. Giles.[4] The numbers are not large, but the figures extend over a period of 10 years and have been carefully recorded and corrected for public institutions. These are set out in Tables II. and III., together with the corresponding figures for St. Giles district and for London. Comparing the buildings in St. Giles and in London for 10 years, from 1890 to 1899, the percentage of population under five years was respectively 17·0, 10 1, and 11·9 per cent.; the birth-rate was 37·3, 27·6, and 30 4 per 1000 of population; the mortality under one year of age per 1000 births was 130, 153, and 160; the death-rate under five years of age per 1000 population under five years of age was 50·7, 76·9, and 65·6; the death-rate over five years of age per 1000 population over five years was 10 4, 16·3, and 13·6; the death-rate at all ages per 1000 population at all ages was 17·3, 21·3, and 19·8; and the death-rate from the seven principal zymotic diseases was 3·0, 2·1, and 2·7.

Comparing these statistics with the results obtained by Dr. Newsholme, and taking his conclusions *seriatim*: 1. The age distribution appears to have varied. In 1881 in London 13 1 per cent. of the population were under five years of age, in 1890–99 the percentage was 11 9 only. 2. The death-rate in Peabody Buildings, which was from 1881 to 1885 about two per 1000 lower than in London, was from 1890 to 1899 in St. Giles's buildings about 2 5 lower than London. 3. The infantile mortality, which was 139 per 1000 births in Peabody Buildings compared with 152 in London, was later 130 in St. Giles's buildings, compared with 160 in London. The birth-rate, however, in the later period was three per 1000 lower in the buildings and a trifle higher in London. 4. The death-rate in the later period from diarrhœa was considerably lower, and from enteric fever only half that of London, the latter in exactly the same ratio as in the earlier period. 5. The death-rates in the later period from scarlet fever and from diphtheria, especially from the former, were higher in the buildings than in London. From whooping-cough the London rate was higher. These results compared in tabular form appear in Table IV.

Therefore, on the whole, the figures of the later investigation in the main follow the earlier, for although whooping-cough comes out much better measles comes out much worse, and the conclusion is confirmed that the diseases due to direct infection are more prevalent in buildings composed of multiple dwellings. An indication that the most important considerations lie in the density of persons in rooms, of rooms in dwellings, and of dwellings in houses, and that not merely density in rooms but in the three-fold sense of density in cubic space rather than square space, lies the key to the prevention of morbidity and mortality.

Although it has been shown that in Peabody Buildings, when compared with London or its districts, the death-rates are lower except those from infantile infectious diseases, two important facts must be remembered: (1) that the population of these buildings is a selected one living under special conditions, and (2) that of the population of all London some are living in old unhealthy houses

and some even in whole areas of old unhealthy houses. In reference to "model dwellings," as they were then called, as Mr. Gatliff [5] put it 25 years ago, the inmates of these houses undergo a two-fold process of selection, firstly, the inmates select these houses as harmonising with their decent tastes, and in the second place, they are chosen from a long list of applicants according to the discretion of the manager. Houses in flats, such as Peabody Buildings, are also kept under strict supervision by resident superintendents, so that both the buildings and the tenants are maintained healthily, accidental nuisances are immediately remedied, and wilful nuisances are promptly stopped. Tenants who do not conform to the rules and regulations or who are otherwise objectionable either leave because they feel out of their element or are firmly persuaded to quit, so that only those who lead well-ordered lives in well-cared-for dwellings, in association more or less with those of similar inclinations, remain. In other words, the comparative healthiness of Peabody Buildings is due as much to improved supervision of usage as to improved methods of construction.

It is for these and other reasons that any comparison between the statistics as to the houses demolished on an insanitary area and of the new buildings erected on the site would be of little value. The changes effected are radical alterations. The width of the streets is increased, the building area is diminished, the height and size of the new houses are increased, and the dwellings are expanded through a larger amount of cubic space. The conditions for the admission of external light and air are improved, the conditions for the supply of pure water and the removal of foul are ameliorated, and the opportunities for dampness and

[5] On Improved Dwellings and their Beneficial Effect on Health and Morals, Journal of the Royal Statistical Society, 1875.

effluvia are absent. But in addition there is a fundamental change in the class of the population; those displaced never become the occupants of the new buildings, and whatever class of new building is erected they never will become occupants. The pick of a neighbourhood will always enter the newest and best type of dwellings and the residuum of the neighbourhood will always seek the oldest and worst.

DISEASED HOUSES.

The association of certain houses with certain diseases is a mode of classification adopted by many investigators. That communicable forms of disease should be associated with infected houses is undoubted, and "consumptive houses" are amongst this class. Pathogenic bacteria find within the dwelling more congenial soil than in the open air, and when they are not introduced by infected individuals they may be by the clothing and by the feet, or by animals and by insects. Although investigation has also been extended to "pneumonia houses," and suspected "cancer houses," these classes of houses must rather be regarded as suffering from infection remediable more by isolation, disinfection, and cleanliness, than by improved construction and usage.

EFFECTS OF CERTAIN DEFECTS OF DWELLING-HOUSES.

Most of the faults of the construction and arrangements of dwellings give rise to impure air and may be classed as air deficiencies and effluvia. Under this head, in addition to the curtailment of cubic space, would come want of perflation and ventilation, want of cleanliness, defects of drainage and of the removal of solid refuse, and unhealthy conditions of the surface and subsoil of the site and surroundings. The only conditions that may be regarded apart from deficient and impure air are coldness, dampness, deficient light, deficient water-supply, and general atmospheric impurity.

Atmospheric impurity.—Commencing with the last-mentioned first, it is an unavoidable consequence of the aggregation of communities that the atmosphere of a town in which the population lives immersed, from which it draws freely and continuously its air-supply, and into which it casts equally freely and continuously its gaseous emanations, should suffer deterioration. The ozone disappears, the oxygen diminishes, and the carbonic acid increases in relative proportion,[6] and gaseous and suspended impurities are added. The reduction of these impurities, especially smoke and fumes, is the work of municipalities, by supervision and by contributing towards restoring the balance in the composition of the atmosphere, by the provision of open spaces and vegetation.

Air-supply.—Air-supply is found wherever a community settles, but water-supply must be sought. The accessibility or facility of water-supply determines the locality of settlement, and the growth of the community is largely determined by the amount and the health by the purity. Private and public ownership, intermittent and constant service, are stages in the water-supply of towns and cities and, as Dr. G. V. Poore[7] has pointed out, high pressure and constant water-supply, combined with prompt water-carriage removal of excreta, has increased the aggregation of the population of European and American cities by enabling dwellings to be piled one upon another many storeys high. This process of piling upwards is of more recent growth in London than in continental cities, and as a newer departure, and less understood structurally, it is of great importance at this period in its possible effects upon health.

Water-supply.—The principles of general water-supply may be said to be now fairly well known both in their application to public supply and private service, so that our cities are spared the serious effects of impure or polluted water—effects so well known as not to require re-statement. The main points that interest us at the moment are sufficiency and accessibility. The constant high-pressure system supplies the sufficiency, but the accessibility is not to be found, especially in ordinary vertical houses, sublet in many dwellings or tenements where the difficulties of the maintenance of cleanliness are increased by the closer and closer aggregation of population and a premium is placed upon the use of water by the vertical and horizontal distance through which it has to be carried to and fro. *Mutatis mutandis*, similar observations apply to drainage, and the distance to be traversed in sublet or tenement houses, especially by those on the upper floors, to get rid of liquid refuse and fouled water, also militates strongly against cleanliness, and cleanliness largely influences the purity of the air of interiors.

Deficient light.—Darkness is known to cause anæmia and to retard the development of animals, and the younger the animal the greater the effects.[8] In the absence of light plants etiolate, without light there is no fructification, and few plants can flower without direct sunshine. Direct sunshine, and even diffused daylight, warms and dries, sets up air-currents, removes stagnant air, dissipates humidity, resolves unstable compounds and conduces to cleanliness, and the absence of light produces the opposite result. Darkness favours the growth of cryptogamic plants, and the most lowly organisms flourish best in semi-darkness, notably, the moulds and the bacteria. On the contrary, the higher plants and animals are most benefited by light, which is destructive to the lower organisms which number amongst them the injurious pathogenic organisms of man. Tyndall, Downes, Duclaux, Koch, Roux, Raum, Ransome, and many others have shown by experiment that light is inimical and darkness beneficial to micro-organic life. The bacilli of anthrax, diphtheria, and tuberculosis have so responded, and many other pathogenic and non-pathogenic organisms, including the pneumococcus, and the pyogenic cocci. The most recent experiments[9] are upon tuberculous sputum, and they have shown that one hour's drying and exposure to direct sunlight has destroyed its virulence, and that from four to seven hours' exposure to diffuse light in all cases markedly diminished its virulence and in some instances destroyed it. Briefly, the indications of experiment and observation are that the healthiness of the dwelling in this country increases in proportion to the amount of daylight and sunlight admitted.

Dampness.—Marshy soil has from time immemorial been associated with malaria and ague, and it is now known that stagnant surface water in the neighbourhood of dwellings is the breeding-ground for the larvæ of mosquitoes that act as carriers of the parasites of malaria from infected to uninfected individuals. Wetness of the soil or subsoil is also known to predispose the dwellers upon it to throat-soreness, rheumatism, respiratory diseases, and phthisis. The earliest indication in this country of the effect of damp subsoil was given by Sir George Buchanan in his inquiry of 1865, upon which Sir J. Simon said[10] that the statistics indicate "that the drying of soil which has in most cases accompanied the laying of main sewers in the improved towns has led to the diminution more or less considerable of phthisis"; and he cited the reduction in the death-rates of the first 15 towns in Dr. Buchanan's table as being in Salisbury 49 per cent. of its previous rate, in Ely 47 per cent., in Rugby 43 per cent., in Banbury 41 per cent., in Worthing 36 per cent., in Macclesfield 31 per cent., in Leicester 32 per cent., in Newport 32 per cent., in Cheltenham 26 per cent., in Bristol 22 per cent., in Dover 20 per cent., in Warwick 19 per cent., in Croydon 17 per cent., in Cardiff 17 per cent., and in Merthyr 11 per cent. Dr. Bowditch of Boston, U.S.A., had in 1862 arrived at similar conclusions, which were subsequently published. Dryness of the site and of the house are recognised as essential to a healthy dwelling. More recently[11] the effect of drying upon the virulence of cultivations of tubercle bacillus and of tuberculous sputum, the specimens being kept in the dark in closed capsules with access of little air, has shown that moderate desiccation slightly retards the first manifestations of tuberculosis and prolonged drying ultimately kills the bacillus. All our largest towns are now sewered, and drying of the soil and subsoil is regarded as essential, as well as the prevention of the rising of dampness through floors and up walls and the soakage of wetness through roofs and down walls.

Coldness.—This is essentially a characteristic of jerry-built houses. These houses are so styled more on account of the inferior materials and bad workmanship in the carcasses than of the rough fitting and finishing, or of the scamped fitting of insanitary appliances. The fitting of green or unseasoned woodwork and joinery, and the finishing with plaster containing no hair, are apt to check themselves at the end of a short time. The laying of porous, crumbling bricks, with mortar deficient in lime, to sustain "shaky" or splitting timber, is controlled more or less by

the surveyor or building inspector, who also now requires damp-courses in the walls, concrete in the basement, and dry areas around the building. The main characteristics of jerry-built dwelling-houses are deficient dryness and deficient equability of temperature. Popularly they are said to be cold and damp, the dampness coming directly through the walls and the coldness being also due to this flimsiness. Increased vigilance and building by-laws have made it much less easy to build this class of house, and this to the advantage of public health, as, apart from other insanitary conditions, the coldness and dampness within the dwelling are not only injurious themselves but indirectly they lead to the closure of all openings and the stagnation of air in order to obtain more warmth.

Air-deficiency.—The ill-effects of deficient wind-play in narrow streets, want of perflation as seen in extreme cases in back-to-back houses, and insufficient cubic space in dwellings curtailed in size, and crowding in the dwelling-rooms, have already been dwelt upon. In addition to respiration the air is fouled by combustion, which in better-class houses generally takes place by the use of excessive gas-light, but in poor tenement houses the smoky chimney almost invariably adds to the foulness of the air, and the components of coal smoke we know are prejudicial to health. The smoky chimneys indicate also the want of ventilation in such houses, in some almost amounting to stagnation. The ill-effects of stagnation of air are also demonstrated by the "dry-rot" that sets in below unventilated floors, the absence of air-currents not removing condensed moisture, and the fungus spores which are deposited flourishing in an equable temperature, in darkness and quiescence. It has also been shown by experiment[12] that finely divided tuberculous matter and tuberculous sputum in free currents of air are rapidly deprived of virulence, and in the absence of currents of air the bacillus retains its power for long periods of time.

Effluvia.—The surface soil is a great collector of decomposing refuse matter and micro-organisms which in dry weather may be wafted by the air and in wet weather may be carried by the foot of man or animals into houses and so contaminate the air of dwellings and food. Pathogenic organisms find in the dwelling the most favourable warmth and nutriment conducive to their growth and distribution. Dr. Sidney Martin[13] conducted a series of laboratory experiments upon virgin soils and organically polluted soils with a view to ascertaining the results when inoculated with the typhoid bacillus. The virgin soils, both peaty and sandy, after inoculation with various typhoid cultures and incubation at various temperatures showed no sign of growth whatever when tested at the end of 14 days, 20 days, and 23 days. On the other hand, the organically contaminated soils from the neighbourhood of habitations, after sterilisation and inoculation with the typhoid cultures, showed that either a part or the whole of the experimental soil had become pervaded by the growing bacillus, the results varying in extent with temperature and moisture, but also showing that the growth and diffusion take place at ordinary temperatures of the atmosphere. Dr. Martin has also shown that this multiplication is still going on at the end of many months. In 1896–97 Dr. John Robertson,[14] the medical officer of health of Sheffield, made a series of out-door experiments, inoculating patches of soil by drenching the surface with typhoid cultivations in bouillon diluted with water, the superficial surface of the soil having been removed and replaced. The results showed that the typhoid organism is capable of growing rapidly in certain soils and that under certain conditions (presumably continued pollution) the organism can survive from one summer to another in spite of rain and snow, frost and heat. Some laboratory experiments on similar soil went to show that vegetation such as grass was detrimental to the growth of the organism. Following upon this Dr. P. Boobbyer[15] made a statistical investigation into the distribution during the 10 years from 1887–96 of typhoid fever cases among houses in Nottingham furnished with different types of closets, and he found that the proportional annual incidence in midden-privy houses was one case in 37 houses, in pail-closet houses one in 120, and in water-closet houses one case in 558 houses—that is, that the incidence upon houses with privies was more than three times as great as that upon houses with pail-closets, and that upon houses with pail-closets more than four and a half times greater than that upon houses with water-closets. Further, he found that the disease is much more liable to recur after it has arisen in the privy houses and the pail-closet houses than in the water-closet houses. In 1897, of the 41 second consecutive cases that occurred in single houses, 37 were in pail-closet houses, four were in privy houses, and there were none in water-closet houses. Of the 11 third consecutive cases that occurred in single houses, eight were in pail-closet houses, three were in privy houses, and there were none in water-closet houses. Of the four fourth consecutive cases in single houses all were in pail-closet houses. He pointed out that the closet-pail is essentially only a small portable privy above ground, and is capable of polluting the air, the soil, and the surroundings almost as much as the privy, especially by spilling and leakage in scavenging. It has been proved by experiments[16] upon rabbits, guinea-pigs, and rats, and has been confirmed, that the inspiration of putrid gases predispose the animals to the pathogenic action of even attenuated typhoid bacilli and of bacterium coli; that this predisposition is due to the combination of gases given out by putrid fermentations, and not to any one separately; and that it is probable that this experimental predisposition is diminished by prolonged breathing of the said gases. In other words, that the gases from drains, from sewers, and from other polluted sources predispose those who inhale them sufficiently, and especially new-comers, to enteric fever. These gases lower nutrition and vitality and probably tend to predispose to other ailments. In addition to enteric fever, it is very generally admitted that sewer-gas may cause sore-throat, and it is well known that persons suffering from sore-throat are susceptible to diphtheria and to scarlet fever. Septic poisoning, or blood-poisoning, has frequently been found associated with sewer-gas, and its congeners, puerperal fever and pneumonia, have often followed. Diarrhœa, too, has been attributed to foul gases either indirectly or directly. Professor Corfield[17] has given a large number of instances illustrating the close connexion between sewer-gases and these diseases. Ground vapours also produce their ill-effects. By experiment it has been shown that condensed organic vapour from ground-air or from human breath[18] forms an excellent cultivating medium for the bacillus of tubercle when away from the influence of fresh air and sunlight or daylight. This power of promoting growth is particularly manifest when the supporting substance is common wall-paper. On this substance the growth of the bacillus may take place at the ordinary temperature of dwelling-rooms. Ground vapours from below dwelling-houses, being foul and damp, are also known to pollute the air of interiors, to deteriorate the health of the inmates, and to predispose them to disease.

All these experiments and observations indicate the necessity for such construction, maintenance, and usage as best conduce to the cleanliness and purity of the air in and around dwelling-houses in order not only to prevent disease, but also to prevent the loss of that vitality, vigour, and energy which cannot easily be measured by experiments or by statistics.

CONSTRUCTION AND MIS-CONSTRUCTION.

1. *Streets, street-blocks, and houses; front and rear space.*—The hygienic influence of sunshine and daylight, of wind and breeze, in dispelling dampness, destroying micro-organisms, and dispersing gaseous and suspended impurities, has been proved by experiment and experience. Therefore the direction and width of streets and the height of houses are important points in their influence upon dwellings and health. The orientation of streets may be either squarely or diagonally in line with the four cardinal points. As the main object of orientation is to provide the maximum of sunshine to houses, the rear as well as the front must be considered. When houses are constructed in parallel rows, with open interspaces, so that there are no houses in the streets at right angles, as is sometimes seen in recently erected blocks (Fig. 1, *a*), the square orientation obtains the fullest and most equable distribution of sunshine. But when houses are built around all four sides of rectangular street-blocks then the diagonal orientation secures most sunshine, although with complete enclosure of the central space the rear receives less perflation—the common form of construction of street-blocks (Fig. 1, *b*).

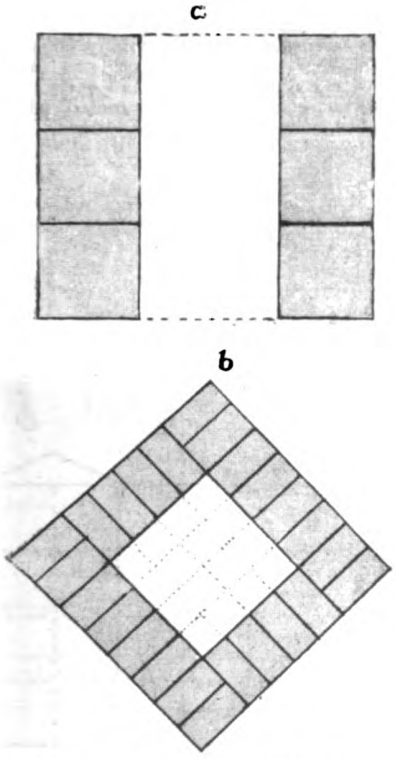
In a street oriented east and west the front of the buildings on the south side of the street and the back of those on the north side are deprived of sunshine, and in order that the front of those on the north side and the rear of those on the south side may obtain sunshine it would be necessary, according to the estimate of Clement, to increase the width

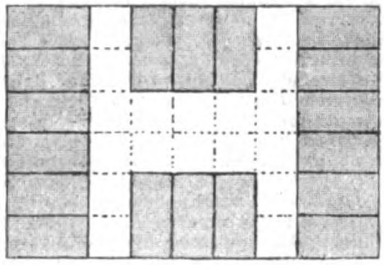
FIG. 1.



a. Shows a method sometimes adopted for new blocks of buildings with streets around. b. Shows a common arrangement of existing street blocks of houses, the internal spaces being more or less built over.

of "east and west" streets and rear spaces in 60 degrees of latitude (e.g., Stockholm) to more than seven times the width of those in 40 degrees of latitude (e.g., Madrid) and, according to the estimate of Trélat,[19] to widen streets north and south twice, and streets east and west four times, the height of the houses bordering them. Both of these are impracticable, so Arnold has concluded that the orientation of streets is beyond exact control, and attention should rather be directed to limiting the height of houses in relation to the width of streets. It must also be remembered that a north light without sunshine is preferable for many industrial and artistic occupations. Whilst admitting that the front and rear spaces of houses in east and west streets require to be wider than those in north and south streets, the practical limit has been adopted that houses should not exceed in height the width of the open spaces at the front and at the rear, but as only half the space at the rear is assumed to belong to one house the house is permitted to be raised twice the height of the width of its own rear space, applying the 45-degree angle to the front and the 63½-degree angle at the rear. This is the principle embodied in the London Building Acts, 1894 and 1898, although its application is limited to new buildings and new streets. Briefly the provisions of these Acts are as follows.[20] No new dwelling-house may be erected so as to exceed 80 feet in height (exclusive of two storeys in the roof) without the consent of the London County Council (Sections 47, 48, 49, and 50 of the 1894 Act). The height of a dwelling-house erected in a street less than 50 feet wide and laid out after August 7th, 1862, must not exceed the measurement between the front wall of the building and the opposite side of the street (Section 49 of the 1894 Act). Working-class dwellings are specially limited as to height, where they are (whether on old foundations or not) within 20 feet of the centre of any highway, at whatever date laid out. The height of the dwelling-house in such case must not, without consent of the Council, exceed the measurement between its front wall and the opposite side of the street (Section 13 of the 1894 Act). All dwelling-houses abutting on streets are further limited in height by the air-space provided at the rear of them. On a street laid out after 1894 the height may not exceed twice the open space behind it. This open space must be of an aggregate extent of not less than 150 square feet. On a street laid out before 1894 the height may not exceed twice such depth with an addition of 16 feet. The open space behind the building may in general be covered up to a height of 16 feet, but this is not allowed in the case of working-class dwellings (Section 41 of the 1894 Act). Working-class dwellings not abutting on streets may not be built until the council or tribunal of appeal has sanctioned the plans for them, but such sanction cannot be refused if it is proposed to provide about the dwellings an open space or spaces equivalent to the open space or spaces

FIG. 2.



A common method of laying out a street block for dwelling-houses in suburbs.

which should have been provided under the Act if such dwellings had been erected abutting on a street laid out before 1894 (Section 42 of the 1894 Act). For the purpose of securing through perflation to streets the London Building Acts also empower the County Council to refuse to sanction a new street unless it exceeds 40 feet in width and is open at both ends from the ground upwards. This prevents future culs-de-sac, although many remain in existence.

The Acts provide that on a domestic building erected in London after Jan. 1st, 1895, in an existing street, and having a basement habitable for sleeping or living purposes, there must be provided in the rear for the purpose of light and air an exclusive open space of not less than 100 square feet free from any erection thereon above the level of the adjoining pavement. If the building erected be in a new street, then in the rear there must be provided an exclusive open space of not less than 150 square feet, extending throughout the entire width of the building and to a depth of at least 10 feet from the building. Of this open space 100 square feet must be left open for a habitable basement. If the basement be not constructed to be habitable the open space at the rear may be entirely built over up to the level of the adjoining pavement, and if the ground floor be not constructed to be habitable the open space at the rear may be built over to a point 16 feet above the street level. There is no provision to leave any open space for the purpose of drainage nor is any alternative provision made to cut off aerial communication between an entirely built-in basement and ground floor to 16 feet above the pavement and a domestic building erected over. One or other provision of this kind is desirable for the protection of health. This is more especially so, as under the new Building Acts new buildings are being erected on old sites throughout London, and enlarged so as to cover the whole surface by building over any existing area at the back up to 16 feet above the pavement, any previously existing air-space being blocked out, and the two or more lower floors being built back-to-back. The whole of some street blocks are being so built in, with offices below and dwellings above, and with an enclosed central well, which is permitted provided the width equals half the height and the depth exceeds twice the width of

[19] Tenth International Congress of Hygiene, Paris, 1900.
[20] The Housing Question in London, London County Council, 1885–1900.

the well. This is a more restricted light and air requirement than the continental system of a central courtyard with *porte-cochère*.

The lines adopted for the admission of light and air to houses have passed three graduated stages. The first stage is illustrated by mediæval houses with projecting upper storeys, the second by straight-fronted existing streets, the third by the backs of more recently erected houses with receding upper storeys such as those erected in a street off the Thames Embankment, between Blackfriars and the Temple. Lifting the area up 16 feet above the level of the street does not apply to working-class dwelling-houses, and as the rear of such houses must have a space equal to half the height when two blocks of such houses back upon each other the two intervening spaces would be of a width equal to the height of the buildings, an angle of 45 degrees. But these intervening spaces are usually thrown into one and it is difficult to see what there is to prevent this space being reduced to half its width, with an angle of 63½ degrees only, instead of 45 degrees, buildings being erected twice the height of the one space in the rear used in common. Of course, the careful provision of external light and air demands the equally careful provision of large windows extending up to the ceiling of dwelling-rooms, and wherever it can be afforded the fixing of ventilating grates in habitable rooms is desirable though not essential.

For the purpose of preventing houses being erected too high or sunk too deep Dr. Poore[21] has suggested the provision of exclusive open space at ground level equal to one-fiftieth of the cubic contents of the house. The height of houses can be controlled by the angle of light and air. The suggestion would prevent the construction of basements, but is this the object to be aimed at? Is it not rather the prevention of the habitation of shut-in basements and making provision for them to be cut off from aerial communication with the dwelling-houses above? This is important, because in the larger types of building containing many dwellings the soil- and other drain-pipes become practically equivalent to the sewer draining a street of dwellings constructed on the old plan.

With regard to the surface of the open spaces immediately contiguous to dwelling-houses the soil in towns always becomes polluted and prejudicial to health. There are two ways in which it can be effectually dealt with, the one is by cultivation as a garden, the other is by impervious paving so levelled and drained as to be readily cleansed. As a temporary expedient the surface may be gravelled and rolled, but this is not of permanent benefit. Many small gardens in town are merely barren wastes, and in deciding as to whether a space is a garden or yard the test is whether it is regularly cultivated with grass or permanently paved. It should be definitely provided that such spaces should be regularly cultivated or permanently paved instead of leaving it to vague by-laws that are difficult, if not impossible, to apply.

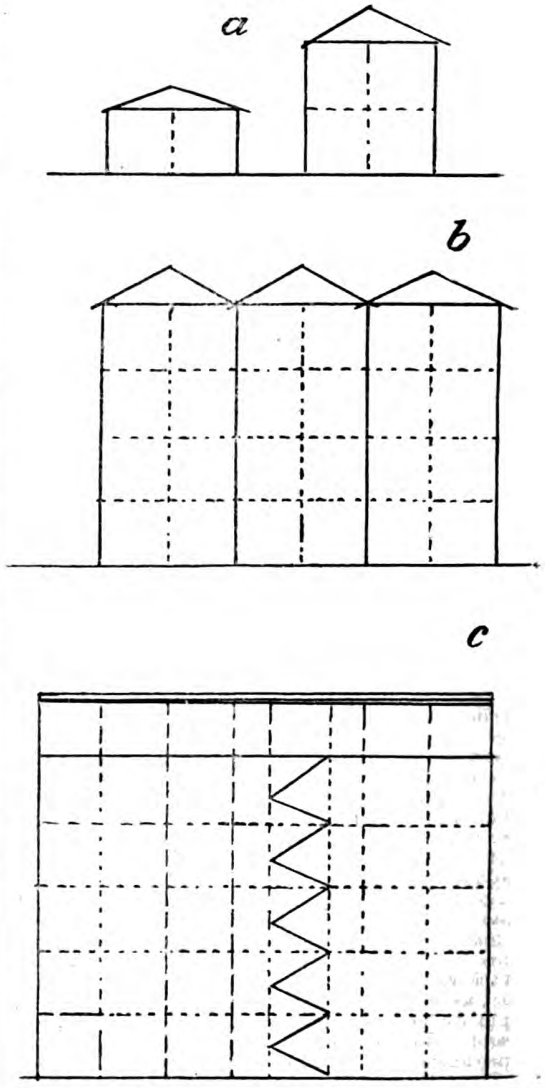
CLASSES OF DOMESTIC BUILDINGS AND DWELLINGS AND THEIR ARRANGEMENT.

Although in considering construction and mis-construction dwellings of the working-classes, especially in new blocks of buildings, have been kept in view, nevertheless the conditions and principles discussed also apply more or less to dwellings of the affluent, especially those that are being erected in increasing numbers in flats of various kinds (see Figures 3 and 4).

There are three main structural divisions of domestic buildings used as family dwelling-places: the horizontal, the vertical, and the vertico-horizontal. The *horizontal* house presents three types according to size: the one-storey cottage, the homestead, and the bungalow, wholly detached from each other. The *vertical* house, in one or more storeys, may be regarded as a cottage, a villa, or a mansion, according to size and according to external relationship to each other. Such houses are detached, semi-detached, and in terrace; the first with four contiguous sides open, the second with three contiguous sides open, and the third with two opposite sides open. These types of houses, when constructed back-to-back, produce respectively the semi-detached, the four-group, and the true back-to-back house, the first having three contiguous sides free, the second two adjacent sides, and the third only one side open. So that in the four-group type of house with two adjacent open sides, instead of the ventilation, or rather perflation, being "through" or squarely across the building it is "diagonal" or obliquely across, and in the true back-to-back type of house with only one open face there is neither "diagonal," "through," or "cross" ventilation or perflation of any kind. This characteristic of having only one open face is not confined to houses built back-to back, but is common to all houses built in terraces with the rear-front closed in on account of abutting on other property over which there is no right of light and air, and hence houses have come to be distinguished as "through houses" and as not through-ventilated (or rather perflated) houses.

The *vertico-horizontal* house essentially consists of horizontal dwellings superimposed upon one another and approached by a common staircase and entry. This compound type of house may also be constructed, with regard to others, detached, semi-detached, or in terrace. Such houses

FIG. 3.



Types of dwelling-house. *a*, a past type; *b*, existing type; *c*, future type.

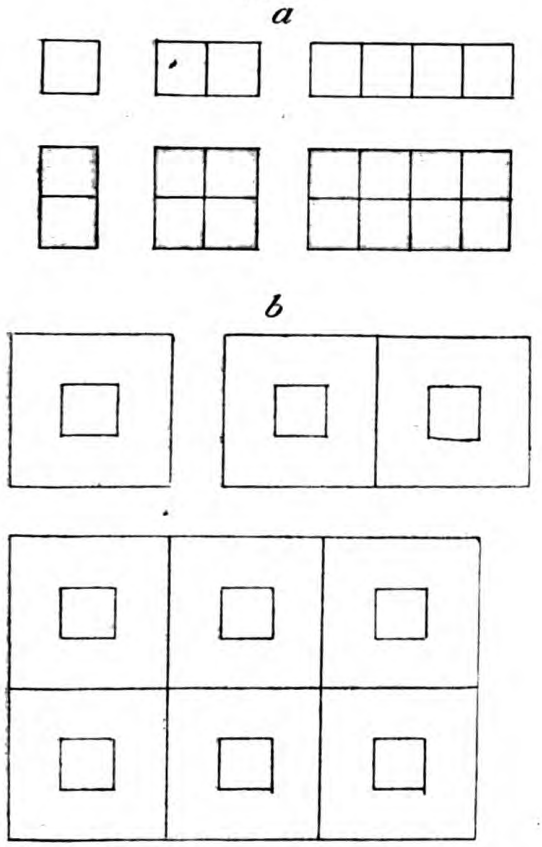
may also be constructed in four-group, or back-to-back, by means of internal staircases and corridors running through the centre, as seen in some of the earlier tenement houses erected in New York.[22] It is obvious that in the compound vertico-horizontal type of house the four-group and back-to-back prevents perflation even more than in the simpler and smaller types of domestic buildings. Although such glaring back-to-back style of building in the vertico-horizontal house becomes almost self-prohibitive this type of house

[21] The Dwelling-house.

[22] E. R. L. Gould, Ph.D.: See Plans No. 5 to No. 12 in the Eighth Special Report of the Commissioner of Labor, Washington, 1899.

enables much more complicated methods of construction to be adopted with the view of economising space while ignoring health requirements. If the constituent dwellings in such houses are prolonged sufficiently far laterally they may be made to extend round two, three, or four sides of a hollow square or rectangular court, and when these hollow squares are placed side by side and back to back there is reproduced on a much larger scale, not four-group and back-to-back houses but four-group and back-to-back blocks of houses. The same effect is produced when one or more of the sides of the internal court are occupied by the blank walls of adjoining buildings. This style of building is met with in continental towns, especially the larger French cities, and is figured in one well-known work[23] amongst

FIG. 4.



a. Showing how detached, semi-detached, and terrace houses become semi-detached, four group, and true back-to-back houses. *b*. Showing how the same thing may take place in a compound building round a central court.

types of Parisian working-class dwellings, and next to it is figured a four-group block. There is no *porte-cochère* or gateway to the internal court, which somewhat mitigates the condition of some of the courtyards of Parisian blocks of dwellings or flats of this type, although it procures little or no perflation to the dwelling-rooms overlooking the courtyards.

Internal enclosed courts are now required by the Building Act in London to be provided with communication into the outer air at the lower end when they have the windows of *habitable* rooms opening into them and the height of the court is greater than the length or breadth; and a court open on one side, the depth of which exceeds twice the width, cannot have the window of a habitable room opening into it lower than half the height of the building. The pectinated form of building is modified to more reasonable dimensions by this last provision, but constructive ingenuity cuts it very fine.

These compound domestic buildings lend themselves to another complication (see Fig. 5). The dwellings may themselves be so arranged as to form semi-detached four-group and back-to-back dwellings. The type of the semi-detached dwellings are dwellings of two rooms, one room on each front, and one dwelling on each side of an open staircase on each floor, although a healthful is not an economical method of building and is seldom adopted. The type of the four-group dwellings may be found in London constructed in the simplest form by placing four single or four two-room dwellings side by side and back to back, the dwellings being approached by an open staircase with four dwellings on each floor, and although the open staircase is beneficial the grouping is not, especially in the case of the inner room in the two-room dwellings. The type of the back-to-back dwelling is found wherever there is a central wall or partition separating the front rooms from the back rooms. This separation ought to be absolutely prohibited by law. If, for instance, in the last-mentioned example the rooms of the front two-room dwelling were made to open into the rooms of the back two-room dwelling, there would be a four-room dwelling with through perflation of the rooms and the staircase. But not only is the perflation of the rooms stopped by cutting off the front rooms from the back rooms, but also the perflation of the staircase by the addition of another room so as to close in one end of the staircase between the dwellings upon each landing. The cutting off of the front rooms from the back rooms may be extended to three, four, or more consecutive rooms, and so a pile of back-to-back dwellings may be erected. In the worst example of this form of construction that I know of, which was only erected a few years ago, there are four four-room dwellings on each floor, an odd room being added to one of the front dwellings; the rooms in each of these dwellings lead one into the other and are all situated on the same front of the building, so that there is absolutely no perflation. When it is added that the building faces north and south, it will be readily understood that the dwellings on the north face not only have no perflation but never see the sun. Outside balconies on the front and rear face of these compound buildings enable the back-to-back method of construction to be adopted to an unlimited extent.

Internal common staircases in compound dwelling-houses, by want of ventilation, are prejudicial to health, as they render the contained air common to all the dwellings opening

upon them. It is essential that a common stairway should be external or against an outer wall and be amply ventilated at each floor level by permanent openings. The insertion of windows may secure light but does not necessarily secure air. The common stairs in artisans' dwellings are usually constructed from three and a half to four feet wide.

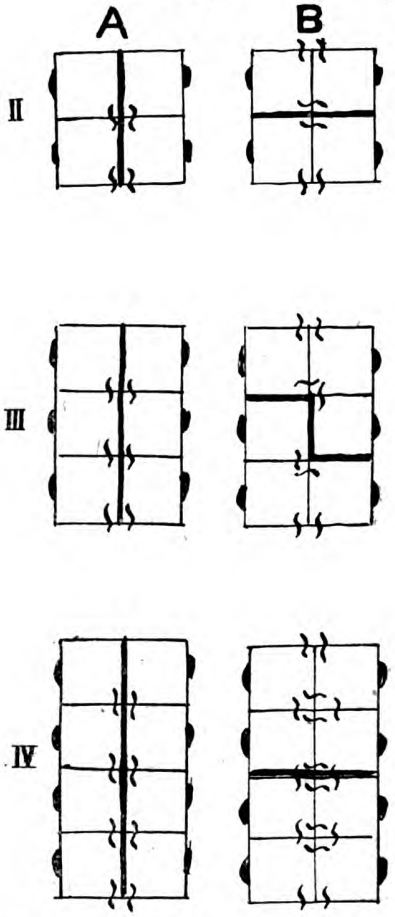
It must be borne in mind that a "flat" in all cases in which the rooms are entered directly from the common stair or in which the vestibule, lobby, or corridor is not ventilated directly from the outer air is essentially one large space divided into smaller spaces, compartments, or rooms and the air-supply is common to all, as there is no ventilated staircase open to each room as in an ordinary house. If there be a corridor in the dwelling it may be found of an I L, T, or H shape, according to the number of rooms, and the placing of hinged fan-lights over the doors of the several rooms or compartments does not procure the ventilation of the corridor into the open air. The fixing of a hinged fanlight, or of a permanent open louvre, over the outer door upon the common stair, when the common stair is closed by windows and doors, merely places the air of each dwelling, by means of the common stair, in communication with the air of all the other dwellings in the building. The windows and doors on common stairs are rarely left open except in the height of summer. This inter-communication of air-supply is a condition that also prevails in ordinary tenement houses sublet in separate dwellings, with one or more families on every floor, and upon which the comment of sanitarians has not been sparing.

In new buildings the Local Government Board wisely insist upon lobbies between water-closets and dwellings being ventilated by permanent openings into the outer air and upon common staircases being similarly ventilated, but the London County Council state[24] that they have provided windows—and, it may be added, doors—to the lobbies and staircases in such buildings because of the unsightly way tenants attempt to block the openings. Section 60 of the London Building Act, 1894, provides that in every building constructed or adapted to be occupied in separate tenements by more than two families the principal staircase used by the several families in common shall be ventilated upon every storey above the ground storey by means of windows or skylights opening directly into the external air, or shall be otherwise adequately ventilated. This is a *non sequitur*. Such a provision overlooks the fact that a glazed window is a means for the admission of light, but is not necessarily a means of ventilation. My experience is that windows of common stairs are never opened except in the height of summer, and such a provision is illogical when the object in view is to provide a permanent form of ventilation to prevent the air-supply of a building from becoming common to a number of different families. Continuous ventilation by means of permanent openings is the only method of construction of permanent value, and the reason is obvious. The windows will only be opened when those affected are all agreed upon it, and common experience shows how little possible it is to agree upon such a point. This is also a reason for providing that through ventilation shall be obtainable within the dwelling, without necessarily being altogether dependent upon the common staircase, even when it is permanently open on one side to the outer air.

In order to provide for through ventilation, and against back-to-back dwellings, I have on various occasions insisted that one of the conditions of construction must be that in every dwelling of more than one room the alternate rooms must be situated upon opposite sides of the building in such a manner as to secure perflation from opposite fronts.[25] Examples of the non-observance of this condition are to be found in numbers of buildings in London, and even in some of the later buildings erected by the London County Council. The answer to this that might be advanced—namely, that the open staircase is intended to provide the perflation, is cut away by the fact that the Council have admitted that they now enclose them. The above proposal is illustrated in the diagram (Fig. 6).

The A column shows a two-, three-, and four-roomed dwelling constructed respectively with only one entrance and back-to-back. The B column shows the application of the requirement that every dwelling of two or three rooms should have one of the rooms situated on the opposite front of the building on which the other room or rooms are situated and every dwelling of four rooms two of such rooms.

FIG. 6.



The sign resembling S indicates doorways. To explain this diagram it must be premised that in a building two rooms deep with dwellings let in single rooms it would be impossible to have the window of a single room opening on to both fronts of the building and so the principle of through ventilation for single or odd rooms cannot be made to apply. The diagram therefore shows two (II.), three (III.), and four (IV.) room dwellings (horizontally) in two stages, A and B (vertically).

With reference to the size of rooms in new buildings the London County Council have adopted a minimum of 96 square feet for bedrooms and 144 square feet for living rooms, and the latter may be taken as a maximum, with a height, now, of eight and a half feet, formerly nine feet. It is a mistake to make large rooms for the poorer classes as it leads to overcrowding, the placing of more beds into the rooms, and the mixing of the sexes. If the same sized family that can live in one very large room live in two smaller rooms they are housed under better conditions of aeration, decency, and physical well-being. It is important, also, to remember that in raising the age at which children remain at school, and at which they can commence to work in factories, tends to keep them at home with their parents, without earning anything towards enlarging the dwelling by another room.

The minimum number of rooms in dwellings for the poorer classes is a subject[26] upon which I entered fully at the Birmingham Health Congress and pointed out that the differences of sex and age are the factors that render family life impossible in a single room and that in Glasgow Dr. J. B. Russell had shown that between 1871

A Clinical Lecture

ON

THE STATISTICS OF GASTRIC ULCER, WITH SPECIAL REFERENCE TO GASTRIC HÆMORRHAGE, ITS FREQUENCY AND FATALITY.

Delivered at the Edinburgh Royal Infirmary on Feb. 12th, 1901,[1]

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN.,
PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, &c.

GENTLEMEN,—On Wednesday last Mr. Mayo Robson delivered an "Address on Gastric Hæmorrhage and its Surgical Treatment" before the Medico-Chirurgical Society of Edinburgh. In that address he advanced certain conclusions with regard to the total mortality caused by gastric ulcer and the frequency of death from hæmorrhage in cases of gastric ulcer which are not in accordance with my own experience—and my experience of gastric ulcer is considerable—and which demand, I think, very serious consideration before they are accepted by the profession. The question is one of great practical importance, for if the mortality from hæmorrhage in gastric ulcer is as great as Mr. Mayo Robson supposes it to be, and if his deliberately expressed opinion that operative procedure should be adopted "after a second bleeding, even during the course of the hæmorrhage if the patient can stand it, or as soon after as his condition will permit the operation to be done," is accepted and acted upon, operations for the arrest of hæmorrhage in cases of gastric ulcer will become of everyday occurrence, with, I fear, unless the mortality from such operative procedure should in the future become very much less than it is at present, an increase rather than a decrease of the mortality. I express this opinion, however, with diffidence, for I fully recognise the fact that "gastric surgery is advancing in safety and efficiency with leaps and bounds," and I feel grave hesitation in expressing an opinion on a question which is to some extent a surgical one in opposition to Mr. Mayo Robson who is justly regarded as one of the greatest living authorities on surgical questions of this kind.

Mr. Mayo Robson's conclusions as to the frequency of gastric ulcer, the fatality of gastric ulcer, and the frequency and fatality of hæmorrhage in cases of gastric ulcer are based on a series of statistics which have from time to time been published by leading authorities on the diseases of the stomach. The figures (percentage mortalities) given by these authorities vary very greatly. In arriving at his results Mr. Mayo Robson has taken the mean of the figures—in my opinion an unreliable method of calculation, or rather he seems to have taken the mean of the extremes, which in this case is a most unreliable method, for some of the figures (the maximum figures) which he quotes were published more than 40 years ago and certainly do not correctly represent the mortality of the disease or the frequency with which death from hæmorrhage in gastric ulcer occurs either in hospital or in private practice at the present time. No one, for example, who has an extensive clinical experience of gastric ulcer will, I fancy, agree with the following conclusions of Brinton—viz.: that the liability to ulcer of the stomach increases with the age of the patient and reaches its maximum at the extreme age of 90 years; that gastric ulcer only undergoes a spontaneous cure in 50 per cent. of the cases; and that the mortality (direct and indirect) in all cases of gastric ulcer from all causes is consequently 50 per cent.[2]; or with Müller's statistics, published in the year 1860, which show that 11 per cent. of all cases of ulcer of the stomach die from hæmorrhage.[3]

It is unnecessary to tell you, gentlemen, that statistics, unless the data on which they are compiled are absolutely reliable, are apt to lead to very erroneous conclusions; and I venture to think that there is perhaps no subject in the whole range of medicine on which the statistics are more uncertain than the subject of gastric ulcer. This is due to the circumstance that the data on which many of the statistics relating to gastric ulcer are largely based are not facts but merely deductions and conclusions from facts, and that the facts themselves on which these deductions and conclusions are founded are in some cases matters of inference rather than of certainty. Further, some of the mortality percentages were published many years ago. The statistics of gastric ulcer require, I think, careful re-investigation and re-consideration.[4] In this lecture I propose to direct your attention to some of the fallacies connected with these statistics and to try to show that Mr. Mayo Robson has considerably over-estimated the total mortality from gastric ulcer and the mortality from hæmorrhage in gastric ulcer. And here I would ask you to note that I limit my remarks to simple (round or perforating) ulcer of the stomach. I do not refer to simple (round or perforating) ulcer of the duodenum; for although the differential diagnosis is sometimes, I believe, impossible and in many cases attended with difficulty, the two conditions seem to me to present certain differences from a clinical point of view, which, when one is considering the total fatality, the risk of fatal hæmorrhage, and the advisability or non-advisability of operative interference, make their separate consideration, probably, advisable; but I reserve my final opinion on this point.

THE FREQUENCY OF GASTRIC ULCER IN THE GENERAL POPULATION.

We have no certain knowledge as to the frequency with which gastric ulcer occurs in the general population. The usual estimate which is accepted by all authorities is that 5 per cent. of the whole population suffer at some period of their lives from simple (round or perforating) ulcer of the stomach. Consequently, on this estimate, in a city of the size of Leeds, with, say, 500 000 inhabitants, 25,000 persons may be supposed to have, or to have had, gastric ulcer. This estimate of 5 per cent. for the whole population may be

[1] Some figures and calculations have been added by Dr. Bramwell.

[2] So far as I know, Brinton does not anywhere state that the direct mortality from gastric ulcer is 50 per cent. What he does state in different parts of his treatises on Ulcer of the Stomach and Diseases of the Stomach is that "in 50 per cent. of the cases the ulcer undergoes a spontaneous cure" (p. 140), that "in 13 per cent. of the cases of gastric ulcer death is due to perforation" (p. 144), that "in 3–5 per cent. of the cases of gastric ulcer death is due to hæmorrhage" (p. 153), that "in 3, 4, or 5 per cent., even in middle-aged persons, exhaustion is evidently the chief (if not the sole) cause of death" (p. 154), and that "in about 30 per cent. of all cases of gastric ulcer it is probable the lesion gives rise to a process of marasmus or partial exhaustion which anticipates, hastens, or increases that failure of the nutritive functions which is one of the most essential elements of death in old age" (p. 155).

[3] Das Corrosive Geschwür im Magen und Darmkanal, 1860, p. 91.

[4] I propose to invite the registrars and pathologists of the large hospitals throughout the country to join me in a collective investgtiation of the whole subject.

correct; I neither affirm nor deny its correctness, although I am disposed to think, for reasons which I will presently give you, that it is probably an exaggerated estimate; but what I do say is that the statistics and deductions on which it is based are open to so many uncertainties and sources of fallacy that it can only be accepted as a rough estimate, about which there must necessarily be considerable difference of opinion and uncertainty.

The frequency of gastric ulcer in the population generally has been (approximately) arrived at in two ways—viz.: 1. By observing the frequency with which open gastric ulcers and the cicatrices of former gastric ulcers are met with in the bodies of persons examined post mortem—if, for example, in 10,000 bodies examined post mortem open ulcers are found in 150 cases and cicatrices in 350 other cases, it is concluded that 500 of the 10,000 persons examined post mortem, or 5 per cent., have at some period or other of their lives suffered from gastric ulcer. 2. The frequency with which gastric ulcers are diagnosed in a given number of patients suffering from various diseases examined during life.

A. *The post-mortem method.*—The post-mortem method is the more reliable of the two and it is the one on which the usually accepted estimate of 5 per cent. for the whole population is based. In 32,052 necropsies made in Prague, Berlin, Dresden, Erlangen, and Kiel (collated and analysed by H. W. Welch[5]), there were found 1522 cases of open ulcer or of cicatrix (presumably the result of former gastric ulcer) in the stomach. Therefore, ulcer of the stomach had occurred in 4·7 per cent. (say, roughly, 5 per cent.) of these 32,052 patients.

Objections to the post-mortem method.—In my opinion, the post-mortem method of calculation is open to the following fallacies and objections.

1. All open ulcers are not found. It is obvious that unless the stomach is carefully examined in all cases there is a serious source of error here—e.g., the number of ulcers will be under-estimated. I do not know whether in the cases analysed by Welch the stomach was systematically examined in all cases, but from the thorough way in which post-mortem examinations have for many years been conducted in Germany we may take it, I think, that this was so, at all events in the more recently examined cases.[6] Consequently this source of error may probably be disregarded, though it is certain, I think, even granting that the stomach was examined in all cases, that in the 32,052 cases collated and analysed by Welch the total number of open ulcers was under-estimated rather than over-estimated.

2. The cicatrices of former ulceration are often missed. This is probably a serious source of error, for unless the stomach is very carefully examined cicatrices, more especially the cicatrices of small and superficial ulcers, are very apt to escape observation. That this is so is clearly shown by the observations of Grünfeld.[7] He examined 1150 bodies of persons over 50 years of age in Copenhagen (where gastric ulcer appears to be unusually common). In these 1150 cases cicatrices of gastric ulcers were present in 124 cases, or 11 per cent. In 700 post-mortem examinations in which the cicatrices were not very particularly looked for they were found in 32 cases, or 4·8 per cent; while in 450 cases in which they were particularly looked for cicatrices were found in 92 cases, or 20 per cent. The relative proportion of cicatrices to open ulcers found by different observers varies very considerably.[8] In calculating the percentage with which gastric ulcer occurs in patients examined post mortem the usual estimate is to give the ratio of cicatrices to open ulcers as three to one; but because of the fact that small and superficial cicatrices are apt to be missed unless very carefully and specially looked for there is much uncertainty as to the correctness of this ratio.

3. It is, I think, open to doubt whether a superficial ulcer in the stomach, when it heals, necessarily leads to the production of a cicatrix, or at all events of a cicatrix which is easily detected after death. This is, I think, a practical point of great importance, for if it is allowed that ulcers of the stomach sometimes heal without leaving obvious or easily recognisable cicatrices it is clear that in this fact there may be a very serious source of error.

In Edinburgh ulcer of the stomach is a very common disease clinically; the majority of patients suffering from gastric ulcer admitted to the Royal Infirmary are anæmic young women; hæmatemesis occurs in a very large percentage of cases; but I think I am correct in saying that the cicatrices of ulcers are, relatively to the great clinical frequency of the disease, comparatively rarely found in the bodies of patients examined post mortem. (I have not yet had time to go over the post-mortem records and get the exact figures.) Even allowing for the fact that the attention of our pathologists may not have been particularly directed to the detection of cicatrices in the stomach, I am disposed to think, from my own observations, both clinical and pathological, that ulcer of the stomach (judging from the number of well-marked and undoubted cases which one sees in the wards of the hospital during life) is very much more frequent in the patients admitted to our infirmary than the records of our post-mortem examinations would seem to show. I doubt whether the difference can be altogether or satisfactorily explained by the fact that the scars are often missed on post-mortem examination. It seems to me extremely reasonable to suppose that a superficial ulceration of the stomach, attended with all the characteristic symptoms of gastric ulcer during life, may heal, if carefully treated for a sufficient length of time in its earlier stages, without leaving behind it any obvious or any easily recognised result in the form of a cicatrix. It is not improbable, I think, that ulceration of the stomach as we see it in young anæmic (chlorotic) women not infrequently pursues this course. This supposition seems to receive some confirmation from the following facts: (1) that a large majority of the patients who are admitted to hospital (I refer to hospitals generally and not merely to the Edinburgh Royal Infirmary) suffering from gastric ulcer are women; and (2) that in the female patients admitted to hospitals suffering from gastric ulcer the percentage mortality is considerably less than in the male patients. In other words, in hospital in-patients gastric ulcer is a more fatal disease in the male than in the female.

I am disposed to think that gastric ulcer in the young (chlorotic) female is, on the whole, a less serious and fatal disease than in men—though I, of course, admit that in a considerable percentage of cases gastric ulcer in anæmic young women leads to the production of perforation and is the cause of very profuse hæmorrhage; in other words, that in many instances in anæmic young women the ulcers are deep and not superficial. I suggest that the explanation is probably afforded by the fact that in young chlorotic females the ulceration is not infrequently superficial. I am further disposed to think that, in some cases at all events, the anæmia plays a part in the production of the ulceration, that the persistence of the anæmia interferes with the healing of the ulcer, and that the disappearance (cure) of the anæmia tends materially to promote the healing of the ulcer.

4. Another objection which has been advanced against the post-mortem method by Welch[9] is "that it is not proven that all of the cicatrices found in the stomach are the scars of healed simple ulcers and that, in fact, it is probable that many are not." I do not myself attach any great importance to this objection; the scars in the stomach which result from other causes than simple (round or perforating) ulcer—such, for example, as syphilitic gummata, erosions and ulcerations the result of irritant poisoning, tuberculous ulceration—are probably not sufficiently numerous to be a practical source of error or seriously to invalidate the figures.

I am disposed to think, then, for the reasons advanced

---

[5] Pepper's System of Medicine, vol. ii., p. 482.

[6] The Prague statistics, which include 11,888 of the 32,052 cases collated and analysed by Welch, are very old (1844, 1853, 1854); they are, however, the data on which most British authorities have based, or very largely based, their conclusions with regard to the frequency of stomach ulcer. The post-mortem statistics from hospitals in this country are, for the most part, useless for determining the frequency of gastric ulcer, for until comparatively recently, at all events, in many hospitals it was not the custom to make a careful examination of the stomach in all cases examined post mortem.

[7] Schmidt's Jahrbuch, 1883, Band 198, p. 141.

[8] Brinton (On Ulcer of the Stomach, p. 20) placed it at one to one. "In 11,888 cases (collated and analysed by Welch, see Pepper's System of Medicine, vol. ii., p. 482) examined in Prague by Jaksch, Dittrich, Willigk, and Eppinger, there were 164, or 1·4 per cent., open ulcers, and 373, or 3·1 per cent., cicatrices." In 1658 necropsies Greiss (quoted by Quincke, Deutsche Medicinische Wochenschrift, Feb. 4th, 1882, p. 80) found ulcers or scars in 138 cases, 31 open ulcers, and 103 cicatrices (? four cases both). In 3085 necropsies Steiner (Virchow and Hirsch's Jahresbericht, 1868, p. 125) found ulcers or scars in 110 cases, open ulcers in 56 cases, and cicatrices in 64 cases (and in 10 cases both open ulcers and scars). In 1230 necropsies Wollmann (Virchow and Hirsch's Jahresbericht, 1868, p. 126) found 48 ulcers or scars, 16 open ulcers, 18 scars, 12 both ulcers and scars (two cases not explained).

[9] Pepper's System of Medicine, vol. ii., p. 482.

above (more especially under headings 2 and 3), that in the 32,052 persons examined post mortem in Prague, Berlin, Dresden, Erlangen, and Kiel (collated and analysed by Welch) a larger number than 5 per cent. had in all probability suffered at some period or other of their lives from gastric ulcer. But it does not necessarily follow from this statement that in my opinion a larger number than 5 per cent. of hospital patients examined post mortem in this country at the present time suffered from ulcer of the stomach.

THE FREQUENCY OF GASTRIC ULCER IN THE GENERAL COMMUNITY.

So much, then, for the post-mortem method as applied to hospital patients. Let us now see how this method has been applied to the general population. All authorities, in this country at all events, have, so far as I know without exception, concluded that because a certain percentage of persons who were examined post mortem in hospitals (usually estimated at 5 per cent.) have, at some period or other of their lives, suffered from gastric ulcer, therefore, that the same percentage (5 per cent.) of the general population will, at some period or other of their lives, suffer from gastric ulcer.

It is important to remember that the patients who are examined post mortem in hospitals are for the most part adults (or at all events over five years of age), that the post-mortem examinations on which the statistics on which the 5 per cent. estimate is based were made in German hospitals, and that a considerable proportion of these post-mortem examinations were made more than 40 years ago. Consequently, the deduction which has been drawn by, so far as I know, all authorities in this country, at all events up to the present time, is—that because 5 per cent. of persons who were examined post mortem in German hospitals, the great majority of whom were (presumably) adults, and a considerable proportion of whom lived more than 40 years ago, suffered from ulcer of the stomach, therefore 5 per cent. of the whole population of this country at the present time are suffering from, have suffered from, or will suffer from, gastric ulcer.

Such a conclusion is, I venture to think, altogether unwarranted. In the first place, it is by no means certain that the prevalence of gastric ulcer in this country at the present time is the same as the prevalence of gastric ulcer was in Germany when a considerable part of the statistics collected by Welch were compiled, or even at the present day. It seems certain that gastric ulcer is more prevalent in some countries than in others, and in some parts of the same country than in other parts. Gastric ulcer seems, for example, to be (or was when Grünfeld's observations were made) extremely prevalent in Copenhagen. It seems to be less prevalent in America than in this country. It is said to be very rare in some parts of Russia. It is certainly very common in young chlorotic women in Edinburgh. The disease (and especially the gastric ulcer of chlorotic young women) is probably more common in urban than in rural districts. Further, it is not unnatural to suppose (although so far as I know there are no recorded observations or statistics to prove this) that, owing to differences in dietary, occupation, and mode of life generally, the frequency of gastric ulcer at the present time is different to what it was 40 or 50 years ago. But this objection to the application of the hospital results to the population generally is one to which I attach comparatively little importance. I pass to other objections which are, in my opinion, of much greater weight.

The second objection is that in the class of patients who are examined post mortem in hospitals gastric ulcer is very much more prevalent than in the middle and upper ranks of society, and probably more prevalent than in the same class of persons living in the rural districts (the hospital patients are, of course, for the most part drawn from the towns). Consequently, to conclude because 5 per cent. of the persons who are examined post mortem in hospitals have suffered from ulcer of the stomach that 5 per cent. of the whole population will suffer from ulcer of the stomach seems to me altogether unjustifiable.

The third objection is that (though I speak subject to correction on this point) the post-mortem statistics on which the usual estimate of 5 per cent. is based included very few children under five years of age. Now ulcer of the stomach (I refer to the round perforating ulcer) is, practically speaking, unknown in children under five years of age; but children under five years of age form a very considerable proportion (approximately 13 per cent.) of the whole population. Therefore, to conclude because 5 per cent. of the persons examined post mortem in hospital, the great majority of whom were (so far as I know) over five years of age, had suffered from gastric ulcer, that 5 per cent. of the whole population (a considerable proportion of whom—approximately 13 per cent.—are children under five years of age) suffer from gastric ulcer is certainly erroneous.

In the fourth place, it cannot, I think, be doubted that the percentage of patients who die from gastric ulcer is much larger in hospitals than outside hospitals. In Leeds, for example, last year 16 deaths were registered as due to gastric ulcer, one as the result of duodenal ulcer, and six from hæmatemesis, some of which (say four) were perhaps the result of gastric ulcer. Of these 20 deaths, presumably due to gastric ulcer, eight occurred in the General Hospital and one in the Fever Hospital. But of the eight patients who died in the General Hospital three came from districts outside Leeds. Now, even allowing for greater accuracy of certification in the hospital deaths, the proportion of deaths from gastric ulcer in hospital as compared with private practice is enormous if one considers the relative number of cases of gastric ulcer which were treated during the year in Leeds, in the hospitals and outside the hospitals respectively. Further, a large proportion of the patients who die from gastric ulcer in hospitals are examined post mortem. Consequently the percentage of hospital patients who are estimated to have suffered from gastric ulcer will (because of the manner in which this percentage is determined—viz., by multiplying the number of open ulcers which are found in the bodies of hospital patients examined post mortem by the number 3, which is supposed to represent the number of cicatrices which occur to every open ulcer) be unduly large, and will be very much larger than the percentage of the general public outside hospitals who are suffering from, have suffered from, or will suffer from, gastric ulcer.

I repeat that we have no certain means of saying what proportion of the *whole* population suffer from gastric ulcer. The 5 per cent. estimate, which is accepted by all authorities, may or may not be correct; but the data on which this estimate is based are very uncertain. Consequently the estimate of 5 per cent. for the whole population can only, at the best, be taken as approximately accurate and is, in my opinion, probably excessive.

B. *The clinical method.*—This method is even less satisfactory than the post-mortem method. The number of cases of gastric ulcer in a given number of clinical cases is subject to great variations in accordance with the facts—whether the patients are hospital or private patients; whether they are in-patients or out-patients; with the locality—whether gastric ulcer is common or rare in the district; with the nature of the hospital—whether the patients are chiefly medical or chiefly surgical; whether the hospital is large or small in proportion to the population from which it receives its patients; whether the patients are chiefly males or chiefly females; whether they are chiefly adults or children, &c. And in the practice of individual physicians the number of cases of gastric ulcer which are diagnosed in a given number of clinical cases will vary and depend on many of the same factors as in hospital practice (the age, sex, occupation, station in life of the patients, locality, &c.), and whether the physician who makes the observations is engaged in general or in consulting practice, whether he has a special reputation for the treatment of stomach diseases, &c. Further, the nature of the symptoms which are considered necessary to warrant a definite diagnosis of a gastric ulcer varies in the case of different observers. A physician who considers that it is, speaking generally, hazardous definitely to diagnose a gastric ulcer in the absence of hæmatemesis will meet with far fewer cases of gastric ulcer than another physician who is in the habit of frequently diagnosing gastric ulcer in the absence of hæmatemesis. Further, after a given number of cases of gastric ulcer have been diagnosed in a given number of patients, there are, so far as I know, no reliable figures for enabling us to determine the exact frequency with which gastric ulcer will occur in the population generally. As a matter of fact, different statistics regarding the frequency of gastric ulcer, in proportion to other diseases met with in clinical practice, present great variations even in the practice of the same physician—in other words, in cases in which the diagnostic difficulty (the question as to what symptoms justify a diagnosis of gastric ulcer) may be disregarded. Thus in my own case the proportion of gastric ulcers to other cases of disease differs

very materially amongst in-patients in Edinburgh and in Newcastle (this is chiefly due to the facts that in Edinburgh I had for several years no male beds and that in Newcastle the number of beds to the population which the hospital supplied was, at the time when I was associated with the Newcastle Infirmary, very much more limited than it is in Edinburgh; consequently in Newcastle we were rarely able to admit any but the most severe cases); between in-patients and out-patients in the Edinburgh Royal Infirmary; and between out-patients in the Edinburgh Royal Infirmary and patients seen in private (consultation) practice. The figures are as follows. In 17,226 cases of general medical diseases of which I have kept notes, seen either in hospital or in private practice, there were 202 cases of gastric ulcer = 1·1 per cent., or, if the Edinburgh in-patients are omitted, in 14,681 patients there were 108 cases of gastric ulcer = 0·73 per cent. Thus, in 2545 in-patients in the Edinburgh Royal Infirmary there were 94 cases, or 3·69 per cent. In 893 in-patients in the Newcastle-on-Tyne Infirmary there were five cases, or 0·55 per cent. In 7665 out-patients seen at the Edinburgh Royal Infirmary there were 76 cases, or 0·99 per cent. In 6123 cases seen in private (consulting) practice there were 27 cases, or 0·44 per cent.[10]

THE TOTAL FATALITY FROM GASTRIC ULCER.

It is extremely difficult to draw exact and reliable conclusions as to the total mortality which is directly due to gastric ulcer and its different complications and as to the frequency with which death from hæmorrhage occurs in cases of gastric ulcer. If hospital cases are taken as the basis of the calculation the objection at once occurs that many of the worst cases which occur in a community are sent into hospital, more especially when perforation has occurred or alarming hæmorrhage has developed. Consequently it is erroneous to estimate the mortality in all cases of gastric ulcer from the mortality which occurs amongst the in-patients of a hospital. On the other hand, it must be remembered that, provided that death does not occur within the first few days after admission, death very rarely occurs amongst medical in-patients. My experience in the Edinburgh Royal Infirmary shows that the worst cases of gastric ulcer, with very few exceptions, rapidly improve under appropriate treatment in hospital. Again, it must be remembered that one cannot take the exact percentage of cases which are discharged from hospital as cured as actually cured in all cases. Many of the cases which are discharged as cured are no doubt only greatly improved. Some of the cases discharged as cured relapse soon after their discharge; in these cases the ulcer was no doubt imperfectly cicatrised. Others relapse after a varying period of months or years. In those cases in which there were no gastric symptoms for a considerable period of time after the patient's discharge from hospital it is reasonable, I think, to conclude that the ulcer was cured at the time of the patient's discharge, and that after a time it broke out again or a new ulcer developed; and in estimating the total percentage mortality of gastric ulcer cases of this kind should probably, I think, be regarded as new cases—new ulcers.

The results obtained from the treatment of in-patients in hospital must in many cases be regarded as merely applicable to the treatment of cases of gastric ulcer during a certain, and it may be a very limited, period of their course. In those cases in which the patient is discharged before the ulcer is completely and firmly cicatrised death may, of course, occur during some subsequent period of their course. Hence to argue that because in 100 cases of gastric ulcer treated in hospital 90 were cured, seven were discharged *in statu quo*, and three died, the total mortality from gastric ulcer, in hospital in-patients, is only 3 per cent., is, of course, erroneous. But since the great majority of severe and aggravated cases of gastric ulcer which are admitted to the medical wards of a hospital (provided that the patients do not die within the first few days after their admission) rapidly improve and are in the course of a short time discharged as "cured," it is reasonable, I think, to conclude that, if the treatment had been carried out for a sufficient length of time, many of the cases which are imperfectly cured at the time of their discharge would also have been completely cured.

The mortality percentages for gastric ulcer given by different authorities are for the most part based on hospital statistics. The percentages of different authorities differ very materially. The older percentages, such, for example, as those of Brinton, based on results obtained more than 40 years ago, cannot, and should not, be taken as representative of the results of treatment and as indicating the mortality at the present time.[11] Mr. Mayo Robson, after stating that, "according to Brinton, Habershon, Müller, Dreschfeld, Lebert, and others, the mortality from all causes in all cases of ulcer is from 10 to 50 per cent.," takes the mean estimate of mortality as 25 per cent. (or, rather, he seems to have taken the mean of the extremes), though he states "that this is under the mean given by the authorities named," and concludes "that in a city of the size of Leeds, say, with a population of 500,000 inhabitants, 6250 persons may be expected to die from gastric ulcer or some of its complications." In other words, in the city of Leeds, with, say, a population of 500,000 persons, one in every 80 persons will die from ulcer of the stomach or some of its complications. But since children under five years of age very rarely, if ever, die from gastric ulcer, and since in a population of 500,000 children under five years of age form (approximately) 13 per cent. of the whole population, 6250 persons in 435,000 (which represents the population of Leeds, stating it at 500,000 *minus* the 65,000 children of Leeds under five years of age) will die from gastric ulcer; or one in every 69 persons over five years of age will, according to Mr. Mayo Robson, die from ulcer of the stomach.

Again, to put the matter in another way, the annual death-rate of persons (males and females) in Leeds was last year 20·05 per 1000. Consequently, the whole of the population of Leeds (estimated at 500,000) will be exhausted by death in 49·87 years. Therefore, the average annual mortality in Leeds from gastric ulcer will, according to Mr. Mayo Robson, be 6250 divided by 49·87 = 125 per annum. Or, again, the death-rate being 20·05 per 1000 per annum, it may be assumed that the same proportion holds as regards those who die from gastric ulcer, that is, 6250 multiplied by 0·02005 = 125 deaths per annum from gastric ulcer. But the death-rate in Leeds last year was in persons over five years of age 13 per 1000,[12] therefore (taking this death-rate as the usual standard) the annual average death-rate from gastric ulcer in persons over five years of age would be 0·013 × 6250 = 81·25. According to Mr. Mayo Robson, therefore, 81·25 persons above five years of age will on an average die from gastric ulcer in Leeds (estimating the population at 500,000) every year (granting, of course, that the total deaths (6250) are equally spread over 49·87 years).

Now what are the actual facts? My friend Dr. J. Spottiswoode Cameron, medical officer of health of Leeds, has kindly furnished me with the exact number of deaths which were registered as occurring in Leeds last year from gastric ulcer and duodenal ulcer. The number is 17. Of these 17 deaths eight occurred in the General Hospital and one in the Fever Hospital; three of the 17 deaths which occurred in the General Hospital were deaths of persons who came from outside of Leeds (from Ilkley, from Mosley, and from Gomersal respectively). So that as a matter of actual fact 14 deaths were registered as occurring in Leeds proper last year from gastric ulcer. In addition six deaths were registered from hæmatemesis (three between 25 and 30 years of age, two

[10] Lebert (Krankheiten des Magens, p. 196) found in 41,688 medical cases studied clinically 252 cases of gastric ulcer = 0·6 per cent. In 35,692 cases admitted to the medical wards of the Edinburgh Royal Infirmary (figures kindly furnished by the medical registrar, Dr. A. L. Gillespie) during eight years (from 1892 to 1899 inclusive) there were 803 cases of gastric ulcer = 2·2 per cent. In 42,219 patients admitted to the medical wards of the Charité Hospital, Berlin (Charité Annalen) during the 10 years 1888–89 to 1897–98, there were 555 cases of gastric ulcer = 1·07 per cent. In 116,323 medical and surgical cases admitted to the K. K. hospitals in Vienna and the hospitals of Lower Austria (Reports of these hospitals) during the years 1893 and 1894, there were 433 cases of gastric ulcer = 0·37 per cent. And in 455,842 medical and surgical cases admitted to the same hospitals during the years 1895, 1896, and 1897, there were 1117 cases of gastric ulcer, duodenal ulcer, and perforative peritonitis from round ulcer (the numbers for each are not specified) = 0·24 per cent.

[11] Brinton's statistics, too, are open to the serious objection that a considerable proportion of the cases on which they were based were individual cases ("many hundreds of scattered cases, but always verified by careful necropsy, by scarcely less numerous observers"), which he (Brinton) had collected from journals and reports (British and foreign), as well as hospital museums. Statistics as to the total mortality of cases of gastric ulcer, based on such data, do not represent the total mortality in all cases of the disease.

[12] The population of Leeds last year was 431,287, or, excluding children under five years of age, say, 375,000. The death-rate per 1000 was 20·05. The deaths in 52 weeks ending Saturday, Dec. 29th, were 8619; of these, 3746, or 43·4 per cent., occurred in children under five years of age, and 4873, or 56·6 per cent., occurred in persons over five years of age. Therefore the death-rate per 1000 in persons over five years of age was 13.

between 40 and 50 years of age, and one between 70 and 80 years of age). Some of these deaths, perhaps the three between 25 and 30, were from gastric ulcer. Supposing that four of the six deaths registered as hæmatemesis were due to gastric ulcer (round, perforating ulcer)—and this is making a very liberal allowance—the total deaths from gastric ulcer in Leeds proper last year would be 18. But the population of the Leeds district from which these 14 deaths from gastric ulcer and four from hæmatemesis (which were perhaps gastric ulcer) were derived was 431,287 instead of 500 000. Therefore, in Leeds, if the population had been 500,000, 20·8 deaths would have been registered as due to gastric ulcer last year.

I am, of course, aware that the number of deaths from gastric ulcer varies, in the same city or hospital, sometimes very materially, from year to year; that small numbers are apt to be fallacious, and that the cause of death as registered does not in many instances accurately represent the true cause of death—peritonitis, for example, is not infrequently returned as the cause of death in cases in which the death is really due to the perforation of a gastric ulcer; some of the deaths returned as due to anæmia and cancer are probably, as Dr. Cameron has pointed out to me, due to gastric ulcer; on the other hand, some of the deaths registered as gastric ulcer are, perhaps, due to cancer; some deaths due to gastric ulcer are no doubt, also, returned as due to exhaustion. But, making ample allowance for these sources of fallacy, the difference between 20·8 (the actual number of deaths registered as resulting from gastric ulcer *plus* four out of the six deaths registered as hæmatemesis and taking the population of Leeds at 500,000) and 81·25 (the number estimated by Mr. Mayo Robson), is, I think, sufficiently great to prove that Mr. Mayo Robson's conclusions regarding the total mortality in Leeds from gastric ulcer must be incorrect. Most modern authorities who have carefully investigated the total mortality from gastric ulcer place it at from 8 to 15 per cent.: Dreschfeld,[13] for example, who gives no estimate of his own, quotes Lebert's estimate, viz., 10 per cent.; Welch,[14] who thinks Lebert's 10 per cent. too low, says "perhaps 15 per cent. would be more correct;" and Riegel[15] places it from 8 to 10 per cent.

THE FATALITY OF HÆMORRHAGE IN CASES OF GASTRIC ULCER.

Mr. Mayo Robson's conclusions with regard to the frequency with which fatal hæmorrhage occurs in cases of gastric ulcer also, I think, require correction. He states: "Hæmorrhage, which according to different authorities occurs in greater or less degree in 50 to 80 per cent. of all cases of gastric ulcer, and is, according to various authorities, fatal when medically treated in from 11 to 3 per cent. (Müller, 11 per cent.; Welch, from 3 to 5 per cent.; Brinton, 5 per cent.; Debove, 5 per cent.; Steiner, 6·36 per cent.; Lebert, 3 per cent.; Dreschfeld, 3½ per cent.; and Rodman, 8 per cent.). If we take the average, 7 per cent. of deaths in cases of gastrorrhagia from gastric ulcer will not be far from the truth.[16] If this is worked out in the population of a city like Leeds it means that of the 25.000 persons who have or had ulcer 12,500 suffer from hæmatemesis, and of these 7 per cent., or 875, die." There is, it seems to me, a serious error here, for the percentages of death from hæmorrhage which Mr. Mayo Robson quotes from different authorities,[17] with, so far as I have been able to ascertain, the exception of Rodman,[18] refer not to the percentage of deaths in those cases of gastric ulcer in which hæmorrhage occurs (which Mr. Mayo Robson estimates at 50 per cent. of the whole), but in the total number of cases of gastric ulcer. If, therefore, 7 per cent. of all cases of gastric ulcer die from hæmorrhage Mr. Mayo Robson's figures will have to be doubled; in other words, in a population like Leeds, say, of 500,000, 1750 will die from hæmorrhage. And if this number is spread over 49·87 years (in accordance with the estimate that 20·05 per 1000 of the population die in Leeds every year), and if children under five years of age are deducted, the deaths per annum in Leeds from hæmorrhage in gastric ulcer will, according to Mr. Mayo Robson, be on the average 1750 multiplied by 0·013 = 22·75. As a matter of fact, three deaths were registered as occurring last year in Leeds from hæmorrhage in gastric ulcer. If we add to these four of the six deaths which were returned as hæmatemesis and which were perhaps gastric ulcer we have a total of seven deaths from hæmorrhage in gastric ulcer. Consequently, after correcting the figures (since the population of Leeds last year was not 500.000 but 413,287), the number of deaths from hæmorrhage in gastric ulcer in Leeds, if the population had been 500.000, would (including the hæmatemesis cases which were perhaps gastric ulcer) have been 8·1.

Errors of registration are perhaps less likely to occur in the case of hæmorrhage than in the case of perforation. It is true that in cases of gastric ulcer death occasionally results from internal hæmorrhage without any external discharge of blood in the form of hæmatemesis or melæna, but these cases are so exceptional that for practical purposes they may be disregarded. Some deaths due to hæmorrhage in gastric ulcer are returned as hæmatemesis (I have amply allowed for these), and others perhaps as exhaustion, anæmia, &c. The disproportion between the 8·1 deaths, the actual number which were returned as due to hæmorrhage in gastric ulcer, last year in Leeds (calculating the population at 500,000), and the 22·75 deaths which, according to Mr. Mayo Robson (if I am right in thinking the percentages which he quotes, with the exception of Rodman's, refer to all cases of gastric ulcer), ought to have occurred from this cause is very considerable. Physicians who have had large experience in gastric ulcer will, I fancy, agree with me in thinking that, although the condition of the patient is often most alarming, death from hæmorrhage in cases of gastric ulcer very rarely occurs, and that even in those cases in which repeated hæmorrhages occur it is only in comparatively few cases that the patient dies from bleeding. At the meeting of the Medico-Chirurgical Society I stated that, so far as I remembered, I had never seen a case of fatal hæmorrhage in an uncomplicated case of gastric ulcer. I find that I was mistaken. One fatal case of hæmorrhage due to gastric ulcer has occurred in my hospital practice. In another case which I saw in consultation in Edinburgh the patient I now find died four days after I saw him from exhaustion following hæmorrhage. That case I regarded at the time as a case of duodenal ulcer. In going over my notes of the case I do not feel satisfied that the diagnosis of duodenal ulcer was correct; it may have been a case of gastric and not of duodenal ulcer. Consequently, in 127 cases of gastric ulcer (including the case diagnosed at the time as duodenal ulcer) which I have seen either in consultation practice or treated as in-patients in hospital, there were (so far as my present information enables me to judge) two deaths = 1·57 per cent., or if the doubtful case (of duodenal ulcer) is excluded, one death from hæmorrhage in 126 cases of gastric ulcer = 0·77 per cent. I include the 27 cases of gastric ulcer and the one doubtful case of duodenal ulcer seen in consultation practice, for in several of these the hæmorrhage was alarming; and I exclude the 76 cases seen in out-patient practice, for in very few of them was the bleeding severe, and because many of them were only seen once and I have no records of their after-history.

[14] Pepper's System of Medicine, vol. ii., p. 502.
[15] Nothnagel's Specielle Pathologie, vol. xvi., p. 697.
[16] 7 per cent. does not represent the mean of the percentages quoted but the mean of the extremes.
[17] As regards Lebert and Steiner I speak subject to correction, but I have little doubt that the same statement applies also to their percentages.
[18] Rodman's statement is: "Hæmatemesis occurs in at least 50 per cent. of all cases of gastric ulcer, and many authorities estimate it as present in 80 per cent. It is, too, fatal in 8 per cent. of the cases in which it occurs, according to the conservative estimate of Leube, and we cannot question that it is indirectly fatal in a much greater number of cases by anæmia and its remote consequences."—The Journal of the American Association, June 16th, 1900, p. 1509.

INFECTIOUS DISEASE IN EXETER.—During 1900 there were 176 cases of infectious disease treated at the Exeter Sanatorium, being 58 less than in 1899. The cases comprised 86 of typhoid fever, 79 of scarlet fever, nine of diphtheria, and two of measles. Of the 176 cases, 66 came from the county, reducing the number from the city to 110.

DEATHS FROM SNAKE-BITE.—Sir Joseph Fayrer, gave an interesting lecture on "Venomous Snakes" at the Falmouth High School on March 1st. He mentioned that the last annual report from the Indian Government showed that 2966 persons died in the preceding year from the attacks of wild beasts and 24,621 from snake-bites. The great mortality from snake-bites did not seem to diminish, in spite of all the efforts of the Government.

The Lettsomian Lectures

ON

DISEASES AND DISORDERS OF THE HEART AND ARTERIES IN MIDDLE AND ADVANCED LIFE.

Delivered before the Medical Society of London

BY J. MITCHELL BRUCE, M.A., LL.D. ABERD., M.D., F.R.C.P. LOND.,

PHYSICIAN TO CHARING-CROSS HOSPITAL; CONSULTING PHYSICIAN TO BROMPTON HOSPITAL FOR CONSUMPTION, &C.

LECTURE I.[1]

Delivered on March 4th.

MR. PRESIDENT AND GENTLEMEN,—My first duty this evening is to thank you for the honour you have done me by selecting me to deliver the Lettsomian Lectures for the present year. My second duty is to spend as little time as possible on preliminary remarks, for three hours are all too brief for the useful presentation of material collected for a purpose like the present. In selecting the subject of my lectures I was mindful of the character and objects of this society. In the Medical Society of London there is a fuller blending of men engaged in family practice with men holding hospital appointments than is the case at most of the other learned societies connected with our profession in London, and there is here an opportunity for free communication of experience and interchange of opinion between these two classes of our Fellows which cannot fail to be profitable to both. Therefore I have taken up a subject of thoroughly practical interest and I will attempt to present it to you from the point of view of the practitioner. The problem of the diseases and disorders of the heart and arteries in middle and advanced life may be said to come before the family practitioner every hour of his work and to present difficulties and create a sense of responsibility or even anxiety which are not sufficiently appreciated by the hospital physician. There comes before him the case of one of his patients, an active business man, 45 years of age, who has been seized with angina pectoris when hurrying to the station after breakfast, or that of an old friend whose proposal for an increase of his insurance at 50 years of age has been declined because of arterial degeneration and polyuria; or he is asked to say whether a man, aged 60 years, occupying an important and possibly distinguished position in the community, ought to retire from public life because he has occasional attacks of præcordial oppression and a systolic murmur at the base of his heart. What, again, is he to do for the stout free-living man, just passing the meridian of life, who consults him for weakness and depression, whose heart is large and weak, and the urine saccharine and slightly albuminous? There is not one of my audience who has not met with such cases as these many times in his practice, and a variety of other cases of cardiac disorder and disease after the age of 40 years where the importance of the individuals, the value of their lives, and the gravity of their complaints and their prospects have exercised him very anxiously. What is the prognosis in cases of this order? What can be done for them in the way of treatment? These are the questions which we would desire to answer usefully. The answer, it seems to me, can be given only after an analysis and study of a considerable number of instances of the kind, in respect of their origin, their clinical characters and course, and the result. This is the method of inquiry which I propose to follow. It will be a study of cardio-vascular disease in older subjects from the clinical point of view, but it will be approached not only from the ordinary clinical side as it is approached in hospitals—that is, by an investigation of symptoms and signs—but also, and especially in the light of that particular order of knowledge which the family practitioner has learned to appreciate and has so intimate and correct an opportunity to acquire, a knowledge of the origin or causes of the different affections which it is always difficult and often impossible for the hospital physician to ascertain and which he is perhaps apt to ignore. For the same reason—although to be complete a study of the diseases of the circulation at and after middle life should include an account of the post-mortem characters found in fatal cases—I shall not attempt to describe the pathological anatomy and histology of senile and other lesions of the heart and arteries.

Before, however, examining the influences and circumstances which disorder and damage the circulation in middle and advanced life, let us see what the normal or natural state of the heart and arteries is after the fortieth year of age. It has been ascertained that the different parts of the circulatory apparatus pass through certain definite phases of change in the different stages of that decline of existence and energy which leads to senility and ends in death. We have to thank Professor F. W. Beneke of Marburg for the results of a laborious investigation of this subject[2] which are generally accepted and which I will attempt to summarise.

We should all expect the cardio-vascular system to undergo important changes with increasing age, but few of us would be prepared to find that these changes are neither uniformly progressive nor progressive in the same direction. To make more easily intelligible the nature and, as far as possible, the origin of these anatomical alterations in the heart and arteries during the second half of life I will first refer for a moment to the condition of the circulation in persons from 20 to 45 years of age. During this period of life the blood-pressure is relatively high (reaching its maximum about the age of 36 years), the aorta and other large arteries increase in diameter from the stress of the blood-pressure on their elastic walls, particularly between the ages of 35 and 45 years, and the heart increases in size year after year at a nearly uniform rate. We have in these facts anatomical evidence of the great functional vigour and activity of the circulation in manhood. At the age of 45 years, which is practically the commencement of the period with which we are concerned, remarkable changes occur. Whilst the arteries continue to increase in circumference (somewhat more slowly than before), the blood-pressure falls and the heart begins, almost suddenly, to diminish in size, and these three features characterise the circulation for the next 20 years—that is, until the age of 65 years. How is this fall in the size of the heart to be accounted for? Partly by the widening of the arterial trunks and the consequent fall of pressure. But not by these only, for although the arteries had been widening even more rapidly between the ages of 20 and 45 years, the pressure was actually at its maximum then and the heart large; and we shall presently find other facts opposed to this view. The peripheral resistance in the systemic arteries must fall from some other cause or causes in middle age than the loss of elasticity of the arterial walls—and these causes are probably reduction of mechanical stress, due to comparative bodily relaxation, loss of vaso-motor tone in the splanchnic area, and the chronic diseases of which the subjects have died whose hearts and vessels are measured post mortem. During this phase of life, also, the blood becomes more venous in quality and its hæmoglobin value is lowered.

At the age of 65 years other changes which occur in the heart and arteries are not less striking than those which I have just described. The decline of circulatory energy and the effects of time itself on the protoplasm of the cells of the body have so lowered the metabolic and functional energy of the tissues and organs and the activity of the blood-supply that a considerable proportion of the capillary network becomes obsolete. The peripheral resistance is thus increased; the blood-pressure rises; therefore the heart once more increases so much in size that at the end of 10 years (i.e., at 75 years of age) it is found as large as it was at the forty-fifth year, and at the same time the hæmoglobin value of the blood again proves to be higher. During this period also the arteries continue to grow wider and thicker and longer—another proof that the size of the heart is not determined solely by their calibre. Regarded as a whole, the process of senescence of the cardio-vascular system presents to us a beautiful instance of anatomical readjustment and compensation, the counterpart in a way of the growth of the circulation in energy and activity during the period of full manhood. The arterial walls which have been stretched in their diameter and in their length by exhaustion of their elasticity under the stress of cardiac systole are strengthened afresh

[1] Lectures II. and III. will be delivered on March 18th and April 1st, 1901, respectively.

[2] Die Altersdisposition.

by the development of stays formed of fibroid tissue in the intima and media; and the heart responds to the altered mechanical condition ahead of it in the arteries, and to the increased peripheral resistance caused by the obsolescence of many capillaries, by growing afresh. This account relates to the size of the arteries after the age of 40 years. Now let us inquire what is the condition of their structural elements. The changes described do not necessarily involve disease of their tissue-elements—unless we are to call every senile change morbid.

My friends, Dr. Bosanquet and Dr. Mullings, have given me an account of the state of the heart and aorta in the bodies of 25 men, aged 40 years and upwards, who died from accident or suicide. The average age was 53½ years; and the aorta presented some degree of atheroma in half of the cases. When we consider how very slight a change in the arch of the aorta is habitually described as "atheroma" and that in a few of the cases the valves were diseased, and the heart enlarged, we are justified in concluding that in the majority of persons of 53 years of age the arteries are still sound. This result is in accord with that obtained by the late Professor Humphry who devoted his attention so long and so successfully to the investigation of old age. He states that in the great majority of cases the arterial system appears to present a healthy condition in those who attain to great age.[3] Even among the majority of centenarians the evidences of arterial degeneration were not manifest.[4] And we know that persons of 80 years of age and upwards are occasionally met with whose pulses are unexceptionable beyond presenting a trace of thickening and enlargement. For my present purpose it may, therefore, be concluded that as age advances the arteries naturally become wider, longer, and thicker, and altogether larger than in early life, and that we must not speak of "vascular degeneration" in an evil sense as often as we find these conditions present. As for the heart we know that it may remain structurally sound, and is more often regular than irregular, to the most advanced years of life.

After the age of 40 years many of the influences that threaten the heart and arteries with disorder and disease are peculiar to this period of life—that is, different and distinct from the causes of cardiac and vascular affections in childhood, adolescence, and manhood. I will now examine them in detail and at the same time refer to certain provisions with which the heart and arteries are endowed for resisting them and recovering naturally from their effects.

PHYSICAL STRESS.

This is still a definite cause of cardiac and vascular damage in the second half of life, in the forms both of sudden violent exertion and of ordinary laborious occupations. I have met with instances of acute and serious strain at all ages over 40 years, up to and even after 70 years. In some of my cases there was no reason to believe that the heart was other than sound before the strain; but in a majority of them (and I have analysed 40 of which I have more or less full notes) one or more of the safeguards of the circulation against strain were already defective or wanting. What are these? In the heart, chiefly a high degree of extensibility or elasticity of its tissues, permitting overdistension of the chambers with safety-valve action of the tricuspid in extreme cases, and a sound and vigorous musculature to effect the increased action and if necessary the hypertrophy which mechanical stress demands; in a word, well-nourished healthy cardiac walls. It is an interesting fact that two thirds of my cases of cardiac strain in the second half of life presented also a history of gout, fully-developed or irregular—in other words, a history of perverted metabolism.

The principal safeguard which the arteries possess against strain is of course the extensibility and elasticity of their tissues. Unfortunately, the metabolic disorders, including gout, which we have just found weakening the cardiac walls, are amongst the commonest causes of arterial degeneration also, and the two influences acting together no doubt are accountable for a considerable number of cases of atheroma and chronic arteritis. It is unwise, ill-timed, ill-planned muscular exercise that injures the circulation, most often on the part of the middle-aged man who, awaking to the consciousness of growing fat and gouty, rushes inconsiderately to violent exercise for relief.

[3] Humphry: Old Age, 1889, p. 23.
[4] Op. cit., p. 48.

NERVOUS INFLUENCES.

It is generally recognised that nervous excitement taxes the circulation, and quite recently Dr. Leonard Hill and Dr. George Oliver have demonstrated instrumentally the rise of blood-pressure that accompanies cerebral activity. No doubt many cases of disorder and disease of the walls of the heart and arteries originate in distress, worry, anxiety, and protracted suspense; and the connexion is most often seen in middle and advanced life because these depressing emotions fall most heavily upon mankind at this period. Nevertheless, however clear the direct connexion between nervous strain and cardio-vascular disease may be in many instances, it is in other instances normal, or, more correctly, indirect only. This is a matter of great practical importance. First, the nervous temperament often drives the subjects of it to physical overwork in the form of incessant and prolonged devotion to work with insufficient hours of rest and sleep. In the second place, alcohol undoubtedly plays an important part in many instances regarded as overwork and worry and nervous exhaustion. And thirdly, many of the complaints of nervous depression, lowness, and worry are really due to gout, to influenza, and the like, which are at the same time the true causes of the cardiac symptoms.

EXTRINSIC POISONS.

What I have just said in connexion with nervous causes of cardio-vascular affections brings us naturally to that important group of agents which may be summarily called "extrinsic cardiac poisons"—alcohol, tobacco, tea, coffee, and lead—and I shall have occasion to refer to some of these poisons at greater length under the head of diagnosis.

Alcoholic heart occurs both in men and women; tobacco heart is extraordinarily common in our own profession and common in clergymen and in retired members of the public services; tea, coffee, and cocoa heart I have met with principally in students.

DISTURBANCES OF METABOLISM, INCLUDING GOUT.

There can be no question but that these are by far the most prolific cause of cardio-vascular disorder and disease after 40 years of age—at any rate, amongst the middle and higher classes in this country. This period of life brings with it in many instances comparative relaxation from work and a disposition to substitute quiet, or even passive, for active exercise; and whilst the demands of growth and development on the alimentary system have greatly declined the pleasures of the table and ease generally are too often indulged in as a privilege of advancing years and the legitimate reward of previous years of work. The results are functional disorders of the liver, gout in regular and irregular forms, gravel, and the many associated disorders of the muscular, nervous, and other systems. The heart, blood-vessels, and kidneys are kept under incessant strain; and chronic Bright's disease and cardio-vascular degeneration are not uncommonly the result.

SYPHILIS.

This fruitful cause of vascular disease, and both directly and indirectly of cardiac disease, has by no means ceased to attack the organs of circulation after the fortieth year. Whatever the date of the primary infection syphilis is a standing danger to the heart and arteries in the middle-aged man, and even in declining years.

ACUTE DISEASES.

For the man and woman of 40 years of age and upwards most of the acute specific fevers are affairs of the past. But the liability to several of them remains and very unfortunately the liability to those acute specific processes which may attack the cardio-vascular system—influenza in particular, and less often typhoid fever, rheumatism, diphtheria, and pneumonia, as well as septicæmia of different forms or kinds which work havoc throughout the entire circulation. I should have had more to say under this head but for the fact that our distinguished Fellow and former President, Dr. A. E. Sansom, has thoroughly investigated it and on more than one occasion laid the results before you.

CHRONIC DISEASES.

I will not occupy your time in tracing the origin of certain cases of cardio-vascular disease in middle and advanced life to chronic affections of different kinds. Besides the obvious effects upon the heart, blood, and blood-vessels of anæmia, exhaustion, &c., we meet with such grave lesions as fatty

degeneration from pernicious anæmia and other blood disorders, profound circulatory derangements, and occasionally disease in Graves's disease, and others.

COMPLEX CAUSES.

In addition to the definite and distinct influences which I have mentioned as threatening the heart in this stage of life there are two which, although intimately associated with other causes of cardio-vascular disease, deserve to stand out independently. The first of these is emphysema, and along with it other chronic diseases of the lungs and pleura which strain the right ventricle; the second is chronic Bright's disease which similarly strains the left ventricle.

[Dr. Mitchell Bruce here referred to cardio-vascular disease as affecting certain classes of society, "soldier's heart" being taken as the type. He continued:]

I have now arrived at the last, and certainly one of the most interesting, of the causes of disease of the heart and arteries in middle and advanced life. There are some persons whose hearts and arteries cannot carry them through the wear and tear of what may be called ordinary everyday life for more than 40 or 50 years. The vital energy of their tissues is exhausted prematurely; they are already old at 45 years of age; degeneration of their muscular and other cells sets in early, reminding us of the essential myopathic paralysis of children. This type of case is described as "family heart," for it also runs in families, three, four, five, or more members of which, as in instances which I have myself observed, may have all died suddenly from cardiac disease, some of them at an early age. Similarly, it is not by any means unusual to find quite young subjects—say, of 30 years of age—with vessels already much enlarged, and, I may add, equally young subjects with their lungs already emphysematous, although there is no history of respiratory strain, reminding us of the very common association of emphysema with arterial sclerosis in old age. These cases of family heart and premature arterial sclerosis are the links that connect disease of the heart and arteries in middle and advanced life of definitely pathological origin with the genuinely senile changes in the tissue-elements which render existence untenable at last, and which may be said to be the result of the exhaustion of their nutritional activity by the thousand natural shocks that flesh is heir to.

PURE UREA IN THE TREATMENT OF TUBERCULOSIS.

BY HENRY HARPER, M.D. R.U.I.

DURING the last 19 months I have used pure urea in a large number of cases of different forms of tuberculosis, and I believe it to be a remedy of superior value to any that is used for this disease at the present time. I have administered it both internally and hypodermically with satisfactory results.

The first thing that attracted my attention to tuberculosis was Dr. (now Sir) Hermann Weber's lectures on Tubercle in the *British Medical Journal* of 1884. Since then I have given much attention to this disease, about 200 cases coming under my care every year. It was in those lectures I first saw any clear statement of the curability of phthisis. A few years previously to this, on my rounds attending hospital, I felt pity for every case of phthisis in the ward. The visiting physician would pass it over with a nod of his head: "Gentlemen, this is a case of phthisis; nothing can be done for it." Since then the accumulating proof of the inherent power of the body to resist the ravages of the tubercle bacillus has become more convincing each year. Fowler's grand little work on "Arrested Pulmonary Tuberculosis" emphasises what every physician had noticed clinically—namely, the curative powers of the body in certain cases of this disease. And although the practitioner who sees much tuberculosis has continually to witness failure on the top of failure to effect a cure, I always hoped from the number of successes which I had seen that a time would come when general success would be more complete. We may trust that that era is now arriving, and that with our increased knowledge of the bacteriology and clinical history of tuberculosis, coupled with the open-air treatment and the efforts made by the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, good should result. I hailed with delight the inception of that association, considering it a noble movement, and I became a member; but my experience of tuberculosis leads me to believe that more radical remedies will be needed than fresh air and the ordinary sanatorium, and that the key-note to this will be in a careful revision of our diet list.

I may state in passing that quite half of my cases of tuberculosis come from the country, and this is hard to reconcile with the view that country air is a remedy for tuberculosis. Indeed, the most destructive cases of this disease which I have seen have been in the open country in the north of Ireland and in the lake district of England. In Ireland a farmer whom I knew had his residence on the top of a very high hill, a long distance removed from another dwelling—an ideal spot for health; yet the father and all the children were carried off by tuberculosis.

"Some individuals are preserved although living in the same air and hygienic conditions as those who succumb; they have only differences in their food. Phthisis and scrofula are to be seen in the most diverse climates under the most diverse hygienic conditions in towns and countries where the diet is the one thing arbitrary and variable. Is it one of the causes of tuberculosis?"[1] The writer of the foregoing sentences, in his "Bacillary Tuberculosis," lays much stress on the power of the bacillus to grow in vegetable substances such as potato. He also points out that potash salts favour the growth of the bacilli. He says: "The food of adult animals contains soda and chlorine in the same proportion for the herbivora as for the carnivora, whilst the quantity of potash in the food of the herbivora is from two to four times more considerable. To obtain the necessary supplies of albuminate for daily use they are obliged to consume enormous masses of vegetable matter containing much potash. That is, perhaps, why they are especially subject to tuberculosis. ..... The horse and pig are preserved up to a certain point by food containing much soda, as oats. The carnivora, dogs especially, rarely become tuberculous. ..... [Oats being rich in albumin increase the urea.] All vegetables are rich in potash and poor in soda. It is the same with the milk of the herbivora. In meat, the food of carnivora, potash and soda are in equilibrium, and they are found in the proportions required by the bodily expenditure of these animals." Is it possible that this excess of potash salts in the food of the cow accounts for the frequency of tuberculosis in children who are hand-fed on cow's milk? It was in the work which I have quoted that I first saw it pointed out that carnivorous animals show great immunity to the tubercle bacillus. Whence this immunity? On the other hand, some herbivora show a marked natural selection to provide a favourable soil for the bacilli to thrive in. For years an answer to these questions has often come up in my mind. On looking over my notes of cases of the family history of patients I find that families showing a marked tendency to gout, gravel, and calculus rarely suffer from tuberculous disease. Harris and Beale in their work on "Pulmonary Consumption" say: "We have ourselves seen an apparently complete arrest or cure of pulmonary tuberculosis considerably advanced in the case of a patient who suffered severely from an intercurrent attack of gout." On the other hand, in families where as many as eight children have been carried away there seems to be a puny, sickly state of body, patients choosing to live on farinaceous food—vegetables, fruit, &c.—in short, bad meat-eaters. With this idea I have urged on tuberculous patients the importance of consuming as much animal food as possible. At the Manchester meeting of the British Medical Association the value of a superabundance of meats in the diet for tuberculous disease was discussed, and I think that the profession was nearer grasping a remedy than at any time since.

Again, why do glycosuria and tuberculosis appear so frequently in the same patient? Surely this is not a coincidence. Does it not look as if the saccharine fluids were a suitable pabulum for the bacilli to grow in? Further, why are the goat and the horse immune, and sheep rarely tuberculous, while the milch cow is notoriously susceptible to the bacillus and the rabbit and guinea-pig highly so? We have yet to discover the cause of this immunity. One may speak vaguely of the susceptibility of certain animals to the growth of tubercle; but my opinion is that it will be

[1] Germain Sée.

found in the chemical composition of the urine, and that urea and uric acid play an important part in rendering an animal immune or the reverse.

I take the case of a particular family. I cannot find any trace of tubercle on either the father's side or on that of the mother. The diseases which I find frequent in this family are gout, gravel, calculus, rheumatic arthritis, bronchitis, and the different forms of Bright's disease. I take a member of that family whose occupation has exposed him for the last 15 years daily to the inhalation of bacilli in large quantities, except for three weeks annually during a holiday. I find him as free from tubercle to-day as he was 15 years ago. Why this immunity? I believe it to be dependent on the above-given family history—that is, that his tissues are charged with urea and uric acid, &c., to such an extent that he is immune to tuberculosis, the bacilli not finding a suitable soil to grow in. My impression is, that if we saturate a patient with urea or uric acid, this, in combination with the fluids of the body, would act as an antitoxin to the bacilli. This seems to be the most likely explanation which we can offer for a case like the following. In one family which I attend seven children have died from tuberculosis between the ages of three and 26 years. The parents, who are fairly strong, were reared in the country. The mother's family was tuberculous, while the father's was free from that disease. A few years after marriage they came to Nottingham. Their eldest child, 12 years old, was taken suddenly ill with acute tuberculosis and died within six weeks. One year after this death the third in age was taken ill with the same disease and died after 10 weeks' illness. The father changed his house to avoid the possibility of infection. The same year two more children, aged 11 and 15 years, were taken ill; one died within nine weeks and the other lingered for 11 months. Most careful hygienic measures had been taken to promote health. The children were kept from school, given careful daily exercise in the fresh air, and were educated at home. Again the father changed his residence, moving three miles into the open country in the hope of saving the remaining children. Two years later another child was taken ill with the same symptoms and died from acute tuberculosis. Again they changed house in the country, and still most careful sanitary precautions were taken to avoid any possibility of infection. Three years passed without any illness in the house. Two more were taken ill simultaneously and the disease in each case ran a rapid course. Only one little girl has been left, but though both she and the parents are alive the daughter is tuberculous.

Why is the negro so liable to tuberculosis? He lives out of doors enough; the question of fresh air treatment cannot apply here. I think the explanation will be found in the food he lives on, this consisting largely of starchy substances, such as rice, vegetables, and fruit. He is a small and irregular meat-eater. Again, the monkey, whose food closely resembles that of the negro, is very prone to tuberculosis. By the way, it has long been recognised that the teeth of the highly tuberculous are ivory white, resembling the clean white teeth of the herbivora. On the other hand, the teeth of the gouty are crusted with concretions consisting largely of lime salts and chemical substances closely allied to calculus.

Along with the administration of urea I apply treatment in the broad sense—that is, pure air and plenty of nutritious foods, urging most of all those rich in albumin, and including daily one kidney well cooked, with half a pint of very concentrated beef-tea; also exercise in the fresh air as freely as possible, and in carefully selected cases, if there is no hæmorrhage, light dumb-bells and Indian clubs are practised. Drugs of recognised value are given—iron and cod-liver oil more frequently than any—occasionally medicines to improve digestion, such as hydrochloric acid, strychnia, and pepsin, and creasote in combination with cod-liver oil. In short, urea has been added to the remedies which I formerly used. On two occasions this treatment has called forth symptoms of gout—viz., pain in the big toe-joint and pain in the lumbar region, accompanied by gouty urine containing nearly double the normal quantity of urea. On lessening the animal food and increasing green vegetables these symptoms soon passed off. Carter says: "There is room in plenty both for pleasure and profit by habituating ourselves in our daily work to the exercise of our imagination in picturing to our minds as intelligently and yet as graphically as we can what we conceive to be the morbid conditions of parts hidden from our view in the patients who come before us; to endeavour to form for ourselves as plausible impressions as our knowledge permits of the morbid processes which are taking place—hypothetical though they may be; to fix such pictures in our minds and to compare them with previous pictures of other cases which appear to us to have points in common, in the hope of educing rules for our guide in practice, to work out in our minds the probabilities of causation and their mode of action." This mode of treatment is in keeping with what we know of other remedies which have been used with success in tuberculosis—e.g., nuclein, a substance which increases the metabolism of the organism, and cod-liver oil rendering the chyle more easy of absorption by the lacteals. Physiology tells us that oil must be present where growth and cell-formation are going on. Iron and the hypophosphites increase oxygenation in the blood and tissues. Pure air and rich food containing a superabundance of urea render the tissues and fluids of the body proof against the bacilli finding a suitable soil—in short, they act as an antitoxin.

CASE 1.—A business man, aged 40 years, came under my care on June 7th, 1899. He had been ailing for one year. His indisposition began with insomnia from overwork. Six months previously he had an eczematous rash which remained till within seven weeks of his being seen by me. Two months before coming under my care he was taken suddenly ill with terrible pain on the right side of the diaphragm and was told by his medical attendant that he had "distended heart." He was rapidly losing flesh. He complained of "stuffiness" and of a feeling as of a "band" round the midriff. There was desperate dyspnœa on exertion. The respirations were 32 per minute, with a very quick-beating heart, missing every sixth or seventh beat. The epigastrium was very tender, with marked cardiac impulse. Percussion was very dull, bilateral to the level of the sixth rib. A hypodermic needle was inserted between the ninth and tenth ribs bilaterally and very dark fluid was drawn off. A diagnosis of bilateral pleurisy with pericardial effusion was made. Daily hectic made it soon apparent that there was something more underlying this. Examination of the sputum showed tubercle bacilli, but there were no bacilli in the pleurisy fluid. Here the prognosis was as hopeless as possible. For three weeks the patient was put on approved remedies, including iodide of potassium, salicylate of soda, and digitalis without any improvement. On June 28th the urea was ordered in scruple doses four times daily. Within seven days improvement was very noticeable in the dyspnœa. The respirations were 28 per minute. On this day a crackle was discovered in the left lower axilla denoting the focus of the tubercle bacilli. By July 15th the patient had made great improvement and was able to walk freely on level ground and go up and down stairs with ease. From this time onward the improvement was rapid, the physical signs of disease within the chest quickly departing. Immediately after giving urea the urine increased in quantity and contained more urea and solids. On Sept. 19th the patient was quite well; all signs of pleurisy fluid had gone, there was no cough or expectoration, and he expressed himself as being "as well as ever he was." In January of this year I had a message from the patient saying that he was in the best of health.

CASE 2.—The patient, a man, aged 25 years, who came under my care on Jan. 12th, 1900, had been ailing for four years. The illness began with wandering pains all over the body, followed by swollen glands of the neck. He knew that syrup of the iodide of iron brought the glands down in size. He had worked long hours in a badly ventilated room. He had hoarse voice for a few weeks and a peculiar croupy cough. The evening temperature was 101° F. The left apex was slightly dull, with altered jerking respiratory sounds, and a focus of softening was audible there. The most noticeable feature of the case was enlargement of the lymphatic glands of the neck, all the chain running from the clavicle to the mastoid being enlarged from the size of a garden bean to a walnut. In the hollow above the notch of the sternum was a gland as big as a duck's egg. On each side of the neck above the thyroid cartilages was situated a similar gland. These three large glands seemed to compress the larynx and to produce obstruction to breathing. On Feb. 15th the patient was much worse. There was loud stridulous breathing and he was quite blue in the face and looked a picture of distress. I had a consultation with Mr. A. R. Anderson with a view to operation for the removal of the large glands. We agreed that they were tuberculous and that complete removal was impossible, and that the only thing remaining, if the breathing assumed a worse form, was to insert a tracheotomy tube. I may state here that I examined the sputum and found tubercle

bacilli therein, few in number, but tubercle unmistakeable. It was at this stage that I began hypodermic medication with urea, commencing with 40 grains dissolved in four drachms of distilled water, thoroughly sterilised. The syringe was sterilised as well, having a fine needle two inches long which I inserted deep into the gluteal region, injected slowly, withdrew the needle half an inch or so, and injected the remaining part of the urea at a more superficial depth in the muscle, the operation being done on both sides on alternate days. Within 24 hours there was a marked improvement in the condition of the patient. That night he was able to sleep at intervals and was eased of the choking. On my visit next morning there was less stridor and more steady respiration; his appearance was less livid. No apparent change in the size of the glands was noticeable before the tenth day of injection. At this date there was evidence of shrinking and accompanying this very marked improvement of the laryngeal trouble. Hitherto the patient had been striving to speak in scarcely audible whispers; now he could make himself heard. During the acute period of obstruction a quantity of very ropy white expectoration was raised. The hypodermic injection was used for 45 consecutive days. The patient was 6 st. in weight at the low point and he is now over 11 st. The hypodermic dose of urea was gradually increased up to 65 grains. No local injury or trouble attended or followed the hypodermic injections.

CASE 3.—A female, aged 20 years, came under my care in April, 1899. Three months previously she had had influenza, since which time she had been ill, had suffered from cough, and had lost flesh. The evening temperature was 101° F. There were a loud crackle and a focus of rapid softening at the left apex. The expectoration was teeming with bacilli, the thorax was flat, and the body was thin and wasted. On June 10th the patient showed no improvement. She was put on scruple doses of urea three times a day. On the 24th marked improvement was manifest. There was no hectic, the cough and expectoration were less troublesome, and the crackle at the left apex had gone. The patient had gained three pounds in weight. Careful examination of the sputum showed fewer bacilli but more cocci. On Sept. 15th the patient seemed quite well. The expectoration was free from bacilli, she had gained 10 pounds in weight, and the physical signs of lung disease had gone.

CASE 4.—A married woman, aged 52 years, came under treatment on August 20th, 1900. Her health had been failing for three years. There had been cough and loss of flesh, the decrease in weight during that time being 2 st. During the last year these symptoms had been much worse. There was terrible dyspnœa on the least exertion and the patient did not sleep well. There was no hæmoptysis but a large quantity of green sputum in the mornings was seen to be loaded with bacilli. Daily hectic was present and the appetite was poor. Physical examination showed extensive softening of the left lung all over with several cavities. There were also a crackle and softening of the right base at the back. The prognosis was grave—as hopeless as possible. The patient was put on compound mixture of iron with minute doses of creasote added. Urea was added in a separate mixture in scruple doses thrice daily. The patient was wheeled out in a bath-chair and gentle carriage exercise was allowed. On the 27th the patient was seen again when there was decided improvement; the appetite was better. This line of treatment was persevered in. After two months the patient was able to walk, and now she gets about freely and can stand a 15-miles' drive into Nottingham. She has gained seven pounds in weight, she eats well, there is very little cough, but the sputum still contains bacilli. Never before have I seen a case like this improve. I attribute the improvement to the urea.

CASE 5.—The patient, a female, aged 21 years, came under my care on April 30th, 1896. She had been in failing health for six months. Her illness began with anæmia followed by cough and much loss of flesh. There was also marked dyspnœa on exertion and the voice was hoarse (laryngitis). Physical examination revealed much crackle denoting tuberculous softening in the right apex. The sputum was loaded with bacilli. Under treatment the patient improved during the first year, but through the next year her condition remained stationary. She was now seized with influenza and there were hectic fever, rapid wasting, and profuse sputum. The strange part of the case was a soft baggy swelling that came in the left second intercostal space near the sternum. The swelling looked like a pointing abscess and was in communication with the cavity of the chest. I began to doubt my diagnosis and thought the case might be actinomycosis. To settle this point I inserted a fine aseptic needle and examined the pus, which was largely composed of cocci and a fair number of tubercle bacilli, but no ray fungus. I quite expected the abscess to point and discharge; it did not, but gradually got smaller and disappeared. The patient was very ill at this time, losing ground rapidly. At this juncture I began to give urea in scruple doses four times daily, along with an iron mixture nearly the same as the compound mixture of iron of the British Pharmacopœia and creasote combined. The patient soon showed signs of improvement. The appetite became better, there was less cough, and the sputum contained fewer bacilli and more cocci. I followed up this line of treatment for months, the patient gaining flesh and strength so much that she was able to cycle slowly on level ground during the summer. Now (January, 1901) the patient is in fairly good health, able to do household work, and is free from suffering. The sputum still contains bacilli. Again I attribute the recovery to the urea.

CASE 6.—The patient, aged 21 years, was first seen by me on Oct. 1st, 1900. He had been ailing for 12 months. The illness began with influenza, followed by cough and loss of flesh. Hæmoptysis was present; he had had 12 attacks in all. There was much dyspnœa on exertion. His father had died from phthisis. There was a large quantity of green sputum. The evening temperature was 101° F. Ziehl Neelsen staining showed under the microscope teeming bacilli and there was rapid softening of the upper half of the right lung. The patient had lost 12 pounds in weight. The prognosis was most grave. I ordered urea to be given in scruple doses four times daily, also compound mixture of iron. The patient, who lived in a country town, took plenty of exercise in the fresh air daily, along with gentle athletics, light dumb-bells, Indian clubs, &c. Abundance of nutritious food rich in albumin, a fresh well-cooked kidney every day, and good beef-tea formed the patient's diet, upon which he showed improvement from the first, steadily gaining in weight, losing the cough, and becoming entirely free from the expectoration. He now (Feb. 1st, 1901) considers himself well; there is no increase in the urea excreted.

CASE 7.—A married woman, aged 40 years, came under my care on Jan. 31st, 1900. Her illness dated from her confinement 22 months previously. She suckled her child for over one year. For six months she was very ill. There were cough and loss of flesh but there was no noticeable dyspnœa. Sleep was fitful and occasionally there were night sweats. The patient looked very thin, with bad thoracic movements. Neither auscultation nor percussion revealed any focus of softening, but the sputum when examined for bacilli showed these in abundance. On Feb. 14th a crackle and a focus of tuberculous infiltration in the right interscapular region were discovered. There was much expectoration and the lung was breaking up rapidly. For four months the patient was treated in the usual way. She lived in the country and spent as much time in the fresh air as possible. She was taking the usual remedies, including iron, cod-liver oil, malt, guaiacol, and creasote. On June 6th, being no better, she was ordered to take urea in scruple doses three times a day. Within 14 days the improvement was very marked. I saw the patient fortnightly and the improvement continued to be steady. By Sept. 26th, great improvement had been made. The symptoms of softening had gone, there was no cough or expectoration, the appetite was good, and the patient had gained nine pounds in weight. She now believes herself to be quite well. The urea appeared to be most valuable in this case.

CASE 8.—The patient, a schoolboy, aged 13 years, was first seen by me on May 30th, 1899. He had never been strong. He had been ill for a week with a feverish cough and now he vomited blood. He was a very nervous boy. Respiration was quick and jerky, there was a crackle in the right supra-clavicular region, and the expectoration contained a few scattered bacilli. On June 27th, when the patient had been taking urea for four weeks, the expectoration had become free from bacilli, and the cough had gone. He said that he was quite well. All evidence of disease had disappeared. Now (February, 1901) he is in the best of health.

CASE 9.—A youth, aged 17 years, who came under my care on June 3rd, 1899, had been seized with influenza six

weeks previously. He had suffered from cough, loss of flesh, and failing appetite. He looked thin and ill-developed. There was hyper-resonance in the apices and a crackle in the left axilla denoted softening. Examination of the sputum showed a limited number of bacilli. A favourable prognosis was made. He was ordered to take urea in scruple doses thrice daily with cod-liver oil emulsion. On the 10th the cough was easier. There were more yellow expectoration and more distinct symptoms of softening of the left axilla The patient looked better and said that he felt so. He had gained one pound in weight. On the 12th the crackle was less distinct and the patient had gained another pound in weight. On the 24th the symptoms of softening had gone, there was very little expectoration, and only two bacilli were found in the sputum. On July 22nd there were no cough and no physical signs of lung disease. The patient had gained eight pounds in weight since the treatment was commenced and he seemed to have quite recovered. When seen in October, 1900, he was quite well.

In all these cases the diagnosis was confirmed by microscopical examination of the sputum. All were indisputable tuberculosis, and nearly all were hopelessly bad cases such as I have never before seen to show any signs of improvement. From an extensive experience of urea in tuberculosis it is the only thing that I can call a remedy, and I think its value is best seen in this disease uncomplicated by the various species of cocci.

These notes are very imperfect, being only a rough-and-ready record of cases taken in the hurry of practice. Careful and systematic examination of the urea excreted by the kidneys previously to beginning the urea treatment is needed. Only in two of the cases in which I have examined the urine with Martindale's ureometer have I found any increase in the quantity of urea excreted. I have examined the sputum frequently and almost invariably have found lessening or disappearance of the bacilli. One thing I feel sure about is that urea given in this way has produced cure in some and improvement in others in a series of bad cases of tuberculosis that hitherto my experience has led me to look upon as incurable.

On examining the diet list of any sanatorium the predominant idea seems to be to introduce into the body as much animal food rich in albumin as possible, I would remark in reality urea producers; this, coupled with free exercise in the pure air, increases metabolism, and here it is probable that urea plays an important part in the treatment. From our knowledge at present of the management of tuberculosis all remedies used in combating the disease must be constructive, not destructive.

In the laboratory I have tried twice to get the tubercle bacilli to grow in freshly prepared meat-broth, adding urea from 1 to 0·001 per cent., at the same time inoculating a tube without urea as control. In the control-tubes bacilli grew all right in the incubator; those with the urea added failed. Unsupported this experiment is useless, so I applied to the Jenner Institute of Preventive Medicine to carry out an experiment by feeding a guinea-pig for a time on urea given with the food and then inoculating the animal with tubercle bacilli. This they very kindly are carrying out and the result will be published later. The bacteriological portion of the work was done in the laboratory of Mr. Trotman, city analyst, and Messrs. Allen and Hanburys supplied me with pure urea.

Nottingham.

A CASE OF PEMPHIGUS NEONATORUM IN AN INFANT THREE DAYS OLD.

BY CHARLES J. GLASSON, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

THIS case I consider to be one which is so uncommon as to warrant publication.

On Nov. 8th, 1899, the infant was born. There was nothing unusual in the labour, and the baby after being washed presented the usual appearance. The infant, a fine healthy boy, was above the ordinary weight, and was quite free from any spot or blemish. There was the usual exfoliation that takes place in every newly-born infant. On the third day the nurse asked me to look at the infant as he had, as she termed it, the "milk rash" very badly. I examined the boy and was surprised to see a large one of a bullous nature on the occipital portion of the scalp, round in shape, filled with a cloudy fluid and surrounded by a bright red ring of inflammation; there were several smaller spots of a like character around the larger one, and others on different portions of the body. The boy did not appear to be in any way affected, took his food, and slept well and easily. I ordered a small dose of Dinneford's fluid magnesia to be given at once. There was no jaundice; the tongue was slightly coated. On the next morning, however, the spots had increased over the whole body; the face, scalp, and limbs being covered, many running into each other; all had exactly the same characteristics. The case was one of acute pemphigus. The general condition of the infant was worse; he was restless, constantly crying, and would not take his food; he was very feverish, his temperature being 104° F.; his bowels were constipated; and the urine was scanty and smelling very offensively. A very large patch of the size of a shilling had appeared on the nape of the neck which had been rubbed, and a thick purulent fluid exuded on to a soft handkerchief which the nurse had applied. I at once had the infant undressed and I pricked each spot separately with a clean aseptic needle, absorbed the fluid by means of absorbent wool, then placed him into a bath of warm rain-water, and thoroughly washed all the spots. I allowed him to remain five minutes in the bath, keeping the water at an even temperature. He was then taken out and carefully dried by means of soft linen, and to each spot I applied boric ointment, the infant being wrapped in soft linen and a warm blanket being placed around him. After this I found that he was much more comfortable; he took the breast quite freely and slept for two hours. This treatment I had carried out each night and morning and gave him internally minim doses of liquor arsenicalis.

As I knew both father and mother and their six children very well, and all were perfectly healthy, I was puzzled to account for the outbreak, especially as most authorities are of the opinion that syphilis is the cause. I made every inquiry but failed to elicit one fact which could point to there being any history of syphilis in either the mother or father or grandparents. All the children were strong and healthy and showed no signs of any syphilitic taint. There had been no miscarriages and all labours had been good. None of the children had ever had the slightest rash or spots after birth.

After three days of the treatment described above there was very marked improvement. The temperature was normal, the functions were working well, all the spots were healing, and inflammation was disappearing. No fresh eruption had taken place; the infant taking his food well and being quite free from pain and irritation, I changed the boric ointment for zinc ointment made with benzoated lard. All went on quite satisfactorily; some of the spots had healed and others were gradually closing and getting smaller until the ninth day, when the whole of the outer cuticle began to peel off like a glove, leaving the cutis vera red and weeping with the papillæ prominent. It began on the forehead, hands, and feet, no part of the body escaping. Naturally when this commenced it made the infant very cross and irritable, but otherwise did not seem to affect him. I still continued the baths, only instead of the ointment I used the following powder: oxide of zinc, finely powdered starch, and a small quantity of camphor. This powder was freely applied all over the body after each bath and had a wonderful effect in soothing and allaying the irritation and discharge. The skin slowly peeled off and it was quite three weeks before it had finished, leaving the new skin perfectly whole and free from any blemish. The internal treatment was continued for three weeks.

Seven weeks after the first appearance of the first spot the infant was quite well and perfectly free from any spot or blemish and had increased in weight and size. The mother nursed him all through, having a good and rich supply of milk. Six months afterwards I vaccinated him with calf lymph which took splendidly and healed up without causing the slightest return of any trouble.

Most authorities on skin diseases give the cause of this complaint in infants as due to syphilis. Dr. Radcliffe Crocker states that he considers that pemphigus neonatorum may arise independently, and in this case I agree with him, and do not hesitate to say that it was not due to syphilis but had arisen *per se*. It was not due to dirt, as a trained nurse had charge of the infant from birth. I have seen pemphigus in infants of undoubted syphilitic origin, but never so severe an attack which was so quickly amenable to treatment and which I fully expected to terminate

fatally as the prognosis in these cases is always grave. I think the quick evacuation of the fluid in the bullæ and the antiseptic treatment applied locally and continued afterwards were the means of cutting short the attack and so saved the life of the infant. What I could not understand and had never seen before was the very complete exfoliation of the outer cuticle over the entire body, which on healing again left the skin perfectly clean and free from any blemish. This case was seen by a brother practitioner, who at once diagnosed it as pemphigus and gave his opinion that it must be due to syphilis and would probably end fatally. This, I am glad to say, was not the case and the infant up to the present time is perfectly well and has never had the slightest return of any rash or symptom, neither does he show any of the characteristics of inherited syphilis.

Cheyne-gardens, S.W.

A FEW CASES OF ETHYL CHLORIDE NARCOSIS.

BY W. J. McCARDIE, B.A., M.B., B.C. CANTAB.,
ANÆSTHETIST TO THE GENERAL AND DENTAL HOSPITALS, BIRMINGHAM.

ETHYL chloride, according to Kappeler, was first tried as an anæsthetic for surgical operations by Heyfelder. Recently Lotheissen of Innsbruck introduced it for general use in minor, or comparatively minor, surgery with great success. Ludwig and Wiesner and others quickly followed suit, and now some thousands of cases have been recorded. Occasionally it has been administered for 30, and once for 55, minutes for operations like colotomy and amputation, and in many of the shorter gynæcological interventions.

Ethyl chloride is said to have many advantages and few disadvantages. Anæsthesia is quickly (in about two minutes) induced and as rapidly passes off, leaving no, or slight, after-effects, has no irritating action, and can be administered in heart, lung, or kidney diseases where ether and chloroform are contra-indicated or dangerous. Its main disadvantage is that, except perhaps in children, muscular relaxation is generally not complete and rigidity may be marked in muscular, and especially in alcoholic, subjects.

The best mask to administer from is that of Breuer, to be obtained in Vienna, a close-fitting one with inspiratory and expiratory valves and a chamber above the former to hold the gauze on which the drug is to be sprayed. Large graduated flasks containing 50 cubic centimetres and a freer spraying capacity than usual should be used, so that the usual dose of from five to six cubic centimetres can be quickly poured out. The whole apparatus is very portable and convenient. Before I tried ethyl chloride on others I asked Mr. Charles St. Johnston, M.R.C.S., to administer it to me experimentally in a dental chair, and I can say that the subjective effects were like those of nitrous oxide in every respect and not at all unpleasant. Lotheissen has collected 2500 cases with one death, that of an extremely bad subject. Complications during the induction or continuance of anæsthesia appear to be rare, chiefly, so far as I can read, of an asphyxial kind and dependent on some mechanical factor.

Ethyl chloride would seem to be increasingly used in Germany and France, like ethyl bromide, in operations for which nitrous oxide alone, or mixed with oxygen, would be, if possible, administered in England.

The following are short notes of my first 10 cases, the first two on Jan. 15th of this year.

1.—A woman, aged 40 years; extraction of three teeth. Anæsthesia was induced in two and a half minutes and lasted about one minute, passing off quietly. The colour was heightened throughout. The inhaler was removed before the conjunctival reflex was abolished; there was very slight phonation towards the end, but there were perfect anæsthesia and recovery.

2.—A woman, aged 21 years; extraction of three teeth. The course was much the same as in the last patient, the pulse being good and regular during the operation; there was no excitement or muscular spasm. The patient seemed to be in an analgetic condition.

3.—A woman, aged 24 years. It took three minutes to get her apparently under—i.e., just stopping short of abolition of conjunctival reflex—but recovery was so rapid (a quarter of a minute) that no extraction could be performed. N_2O was therefore administered and two teeth were removed.

4.—A strongly-built woman, aged 20 years; tooth extraction. After three minutes' inhalation with little apparent effect, I changed to N_2O to complete the operation.

In the above cases I was proceeding very carefully because the exhibition of the drug was new to me and in Cases 3 and 4 too little was administered. Again, I was not using a graduated flask and so did not know how much ethyl chloride was sprayed on.

5.—A man, aged 26 years; a difficult extraction. He was the ordinary type of patient. There was good anæsthesia from 20 to 35 seconds. There was no excitement; the colour and respiration were good. Administration was stopped when the conjunctival reflex became much dulled.

6.—A woman, aged 23 years; extraction of two teeth. She was under (the reflex was not gone) in about two minutes. 30 seconds of quiet anæsthesia were obtained; about five cubic centimetres were used. The patient felt a little giddy for a short time afterwards.

7.—A woman, aged 18 years; extraction of six teeth. The patient was very nervous, thin, and had a high arched palate. She felt sick and retched during the taking of an impression of the mouth before operation. There was quiet induction in two minutes; the reflex was just lost, the eyes were turned in, and the pupils were well contracted; the colour was good; the respirations were slow and regular. Perfect anæsthesia for more than one minute was obtained. The recovery was very gradual and quiet; two or three more teeth could have been extracted. She then retched much and vomited a little for a few minutes. She afterwards said that she felt well and much better than after N_2O on two previous occasions.

The usual dental sitting-up posture was kept in all these cases.

8.—A girl, aged eight years; tonsils and adenoids. The administration was slow. Anæsthesia lasted for 25 seconds. Reapplied for tonsils; anæsthesia lasted for 20 seconds. Recovery was as perfect and rapid as from N_2O. There was no change of colour throughout.

9.—A boy, aged 12 years; tonsils and adenoids. The course was the same as in the last case, only the anæsthesia was much shorter.

10.—A spare woman, aged 32 years; scraping, &c., granulations of both ears. From five to six cubic centimetres were sprayed on the inhaler. There was quiet induction in three minutes; the conjunctival reflex was just lost. There was perfect anæsthesia with slight muscular rigidity throughout which did not inconvenience the operator. The colour, pulse, and respiration were very good. Reflex was present most of the time corresponding to moderately contracted pupil. The reflex was twice abolished when the pupil became well contracted and breathing became a little slower. Complete recovery occurred in about one and a half minutes. Operative anæsthesia lasted for five minutes. The patient vomited a little bile-stained fluid shortly after being put to bed. She then felt well, but five hours later she complained of feeling faint for a short time. She was quite well the next day. This was a most successful case in every way.

I used Breuer's mask for all these patients and found it very convenient to manipulate. At no time had I anxiety, nor did I see any change for the worse either in respiration or circulation. I have several times used ethyl chloride instead of nitrous oxide as a preliminary to etherisation and with the same successful effect. The few cases which I have briefly and imperfectly recorded have been so successful that I shall lose no suitable opportunity of testing the drug in carefully selected patients for longer and more difficult operations.

Birmingham.

A FURTHER NOTE ON THE PRODUCTION OF LOCAL ANÆSTHESIA IN THE EAR, NOSE, AND THROAT.

BY ALBERT A. GRAY, M.D., F.F.P.S. GLASG., F.R.S. EDIN.,
AURAL SURGEON TO THE GLASGOW CENTRAL DISPENSARY.

IN THE LANCET of April 21st, 1900, p. 1125, I described a method by means of which the difficulty of obtaining local anæsthesia in the ear could be overcome. It consisted essentially in using a solution of cocaine in anilin oil and rectified spirit. I further mentioned the limits within which

that method was applicable. As the method has been widely adopted both in this country and abroad I propose to describe some little improvements I have been able to make which allow the limits of its application to be considerably widened. Several correspondents wrote to me asking "what is anilin oil?" as they had not been able to obtain it at the druggists, nor could they find the name in works on chemistry. In reply to these inquirers I have only to say that anilin oil is the same as anilin. It is the French *huile d'anilin* and the German anilinöl. It is, of course, not an oil at all, but is frequently termed such because of its oily consistence. When fresh it is almost colourless, but it turns yellow or brown with time. It should be kept in a glass-stoppered bottle and in a dark place.

In the paper referred to I described the method I then employed, using simply a 10 per cent. solution of cocaine hydrochlorate in a mixture of equal parts of anilin oil and rectified spirit. For ear work this proved highly satisfactory, but for operations involving deeper parts, such as excision of tonsils, the removal of bony spurs from the nasal septum, &c., although much better than the simple aqueous solutions of cocaine it still did not completely annul the pain and, moreover, caused a burning sensation. The most obvious way to accomplish this end was to make the solution stronger, and this was what I did. To avoid the dangers of using strong solutions of cocaine, I mixed β-eucaine[1] with the cocaine in the following way. Two solutions were made: (1) a 20 per cent. solution of cocaine hydrochlorate in rectified spirit; and (2) a 15 to 20 per cent. solution of eucaine in anilin oil. The latter is not a true solution, however, as eucaine is only soluble to about the extent of 10 per cent. in anilin oil; a proportion of the eucaine, therefore, lies at the bottom of the bottle. Before use the bottle containing solution No. 2 is well shaken up and 10 minims (measured) are poured out; to this are added 10 minims of No. 1 solution and the mixture becomes clear in a few seconds. This gives the following formula: cocaine hydrochlorate 10 parts, β-eucaine 10 parts, anilin 50 parts, and rectified spirit 50 parts. Of course this solution may be kept in stock, but it turns brown very soon and appears to a slight extent to lose its highly penetrating quality. I therefore keep the solutions separate until just before use, though perhaps the precaution is unnecessary. With this solution I have been able to dispense with all aqueous solutions of cocaine in ear and throat work.

The method of use is different according to the region in which the anæsthesia is desired. In the ear the method I formerly employed was to pour the solution into the meatus while the head was turned to one side. I frequently employ this method still, but another equally efficacious way was suggested to me by Dr. Arthur Hutchison—viz., to soak a small strip of gauze with the solution and to push it down the meatus through the speculum to the required depth. This method certainly diminishes the amount of cocaine and anilin oil absorbed.

In my previous communication I stated that the method was not suitable for throat and nose work on account of the burning pain which it temporarily caused. Further experience has led me to change my opinion in this respect, as I find that the disagreeableness of the burning sensation is fully compensated for by the much deeper anæsthesia obtained and the freedom from symptoms of cocaine intoxication. The method which I employ in throat and nose work is as follows. 10 minims (measured) of the eucaine-anilin solution are poured out and 10 minims of the cocaine-spirit solution are mixed with them. The mixture, at first opaque, becomes clear and consists of a 10 per cent. solution of cocaine and 10 per cent. of eucaine. Under no circumstances do I use more than 20 minims of this solution—that is to say, 10 minims of anilin. That amount is quite sufficient for the painless excision of tonsils, removal of spurs on the septum, cauterising, and other operations. In applying the solution the anæsthetic effect appears to be considerably enhanced if it be rubbed gently over the part for a few seconds. This is done by saturating a small pledget of cotton-wool at the end of a probe with a few minims of the solution and rubbing it in. A period of at least seven minutes should then be allowed to elapse, at the end of which the anæsthesia will be found to be complete; much more so than that obtained by much larger quantities or stronger aqueous solutions of the anæsthetics. It should be added that if, after producing anæsthesia, chromic acid be used as an escharotic, the scab will be dark green in colour owing to the formation of an anilin dye. This produces no deleterious effect in the system and does not diminish the efficacy of the caustic.

In regard to the physiological effects of this method a few words are required. I have not had any trouble myself with symptoms of intoxication, either by the anilin or by the cocaine. I have, however, heard of two cases in which a little trouble resulted. Of one of these I am unable to give details as it was reported to me by a third person. It was a case evidently of cocaine intoxication and the patient recovered in the course of an hour or two. The second case occurred in a patient, aged six years. The solution was instilled into the meatus until the latter was full. In the course of an hour or so the patient's lips became blue and slight gastric catarrh occurred, but no other symptoms were present and the patient was well again in a few hours. As a matter of fact, beyond the peculiar blue colour of the lips there was nothing alarming to note. Excepting these cases, neither of which occurred in my own practice, I have not seen or heard of any trouble with the solution. On the other hand, I never have now any of those symptoms of cocaine intoxication with which rhinologists are so familiar when the *aqueous* solution is applied to the nasal mucous membrane, and which, though not usually alarming, are yet sufficient to prevent the carrying out of minor operations, much to the chagrin of the surgeon and the patient. Using the solutions in the manner described above excludes these extremely disagreeable symptoms.

A few words may be said in regard to the peculiar blue colour of the lips which sometimes occurs. Several of my patients have told me that an hour or two after the use of the solution their friends noticed this peculiar colour. No symptoms were present in any of the cases and the patients would not have known about it had their attention not been drawn to it by their friends. It always passes off in the course of a few hours and leaves no effects. Professor Stockman informs me that this is due to the transformation of oxyhæmoglobin into methæmoglobin. Its occurrence may be avoided if so desired by limiting the dose to 20 minims for adults or adolescents and corresponding doses for children. As regards children it must be remembered that they are said to stand cocaine badly. For my own part I have not seen any objectionable symptoms in children, but then I have always been careful about using cocaine in any form in these patients.

Glasgow.

TWO CASES ILLUSTRATING THE USE OF THE X RAYS IN SURGERY.

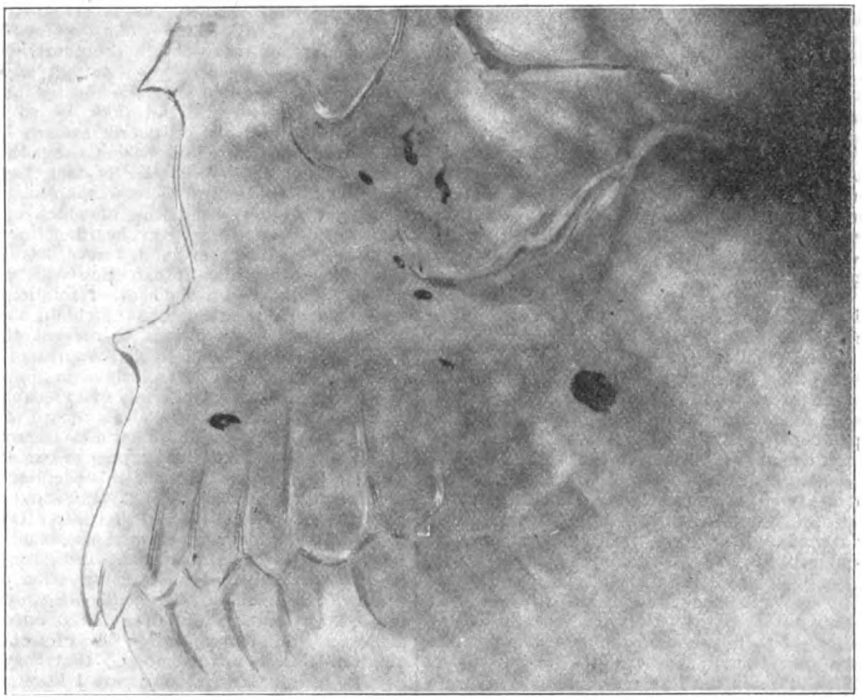
BY G. P. NEWBOLT, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL;
AND
C. THURSTAN HOLLAND, M.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY MEDICAL OFFICER IN CHARGE OF THE X-RAY DEPARTMENT ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

CASE 1.—The patient was a boy, aged 18 years, who was shot in the face. On August 28th whilst lying down another boy pointed a revolver into his face and it accidentally went off. The left eye being injured he was taken to the Liverpool Eye and Ear Infirmary where the eye was removed on the following day by the honorary surgeon, Mr. C. G. Lee. The bullet was not found in the eye, and on August 30th an x-ray examination was made by Mr. Holland. The boy lying down on his left side, two wires were fixed at right angles to one another across the left side of the face, and the skiagram shown in Fig. 1 was obtained. The apparatus used was a 10-inch coil worked with accumulators and the exposure was 90 seconds. The wound of entrance was at the left side of the bridge of the nose, just internal to the angle of the eyelids. The bullet had passed through the left eye and across the superior maxilla, leaving small pieces of lead in different parts on its way along. The spot under which the bullet lay was, from the x-ray examination, given as follows: draw a line straight forward from the lower margin of the lobe of the left ear and measure one inch from

the lobe along this line. From the sharpness and size of the shadow it was estimated that the depth would not be more than about an inch beneath the skin.

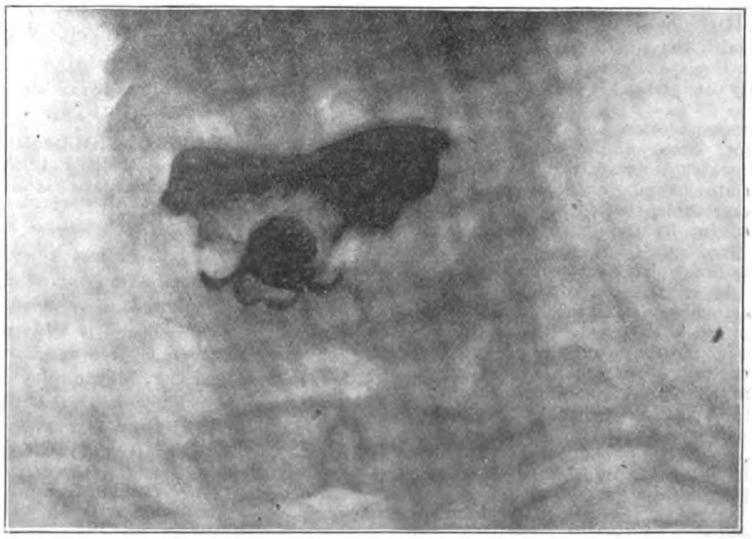
On Sept. 4th Mr. Newbolt made a small incision in the cheek with this spot as its centre. Dissecting straight down through subcutaneous tissue and through the masseter the bullet was found beneath this muscle, at about the depth from the skin of one inch. No difficulty occurred except that it was very firmly embedded and was not easy to dislodge. The wound healed by first intention and the boy made an uninterrupted recovery.

FIG. 1.



Reproduction of skiagram by Mr. C. Thurstan Holland. Shows bullet and scattered fragments in the face for two days.

FIG. 2.



Reproduction of skiagram by Mr. C. Thurstan Holland. Shows vulcanite plate, with one tooth and hooks, in the œsophagus for six hours.

CASE 2.—On July 27th Mr. Holland was sent for to see a boy, aged 16 years, who had when cleaning a window fallen backwards into an area and been badly hurt. When seen some hours after the accident, the cut, &c., having already been attended to, he was complaining of some difficulty in swallowing. As he was still in a very dazed condition it was difficult to get any reliable statement from him, but it was noticed by his friends that a front upper false tooth on a small vulcanite plate with two hooks was missing from the mouth. This could not be found anywhere, so it was decided to examine the boy with the x rays. On looking at him with the screen a foreign body resembling a tooth-plate could be easily seen fixed behind the larynx and it moved up and down

during efforts at swallowing. The skiagram (Fig. 2) was taken with the same apparatus as in the preceding case and with an exposure of 60 seconds. The boy was then transferred to the Southern Hospital and there under an anæsthetic Mr. Newbolt could just reach the top of the foreign body through the mouth with his finger. Without any difficulty he then managed to catch hold of it with a pair of strong forceps and to remove it. The boy made an uninterrupted recovery.

Liverpool.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF MENINGO-MYELOCELE.

BY JAMES BURNET, M.A., M.B., CH.B. EDIN.

ON Jan. 29th, 1901, at 11.45 P.M., I was called to attend a woman in labour. It was her third pregnancy. She had had twins, who died from "decline" six months after birth. Her next child, born four years ago, is alive and healthy. About 18 months ago she had an abortion at the third month and was ill for a long time afterwards. In May of last year I saw her and treated her for constipation and anæmia, with the result that she improved considerably in health. About the end of December she sent for me, as she began to complain of a severe pain in the suprapubic region and over the right iliac fossa. She looked then very much run down. I prescribed for her, but she was unable to leave her bed much until labour set in on Jan. 29th. The presentation was a vertex one. There was some delay in the birth of the head, which was larger than the average. When born the child—a female—was asphyxiated, and gave evidence of convulsive twitchings in both arms and legs. Artificial respiration was performed, and the child soon revived and cried in a feeble manner. On examination I found a tumour situated in the lumbar region. It measured fully three and a half inches in length and two inches in breadth. It was sessile, and presented a well-marked central cicatrix. There was talipes of both feet, with some rigidity of the knee joints. The knee reflexes appeared to be absent. The surface of the tumour was only partially covered by skin. The sac wall was very thin. The tumour was carefully dressed and protected from external pressure. In spite of our efforts, however, rupture was evident on the third day and the child died quietly on the morning of the seventh day, having previously refused the breast. Two days prior to death I observed considerable mottling of the face and trunk, with depression of the fontanelle. Examination of the heart was entirely negative. No post-mortem examination was obtained, which I greatly regret.

The mother is a very neurotic woman, constipated and anæmic, always taking a very despondent view of life. No doubt these facts help to explain this early failure of development. I may add that the placenta and cord were perfectly normal.

Edinburgh.

A CASE OF IRREDUCIBLE DORSAL DISLOCATION OF THE PROXIMAL PHALANX OF THE INDEX FINGER.

BY C. F. M. ALTHORP, M.B. LOND.,
SURGEON TO THE BRADFORD ROYAL INFIRMARY.

ON July 6th, 1900, a youth, aged 16 years, whilst at work in a warehouse in Bradford, fell off a ladder, alighting on the right hand and dislocating the proximal phalanx of the index finger. When seen at the infirmary soon after the accident the right index finger presented the following appearance. The base of the proximal phalanx formed a prominence on the dorsum of the hand, the head of the metacarpal bone projected into the palm, and the finger was shortened and there was limitation in movement. Attempts at reduction by manipulation were made by several of my colleagues as well as by myself, but without success. Gas, followed by ether was given and after the skin had been thoroughly cleansed an incision, an inch in length, was made over the radial side of the joint. The soft structures were drawn apart and the joint was freely exposed. A strong fibrous band, the glenoid ligament, was seen stretched over the head of the metacarpal bone, preventing reduction of the dislocation. The ligament was partly divided with the knife, and then with a blunt elevator I levered the stretched band over the articular end of the metacarpal bone. At once the dislocation was reduced. The wound was closed, without drainage, and when dressed a few days afterwards was found to be healed. Massage and passive movements were employed, the stiffness gradually disappearing.

In December, 1900, six months after the operation, the patient was shown to the members of the Bradford Medico-Chirurgical Society. There were some thickening around the joint and slight limitation in extreme flexion. He had perfect use of the finger and could write as well as before the accident.

The case is of interest as illustrating the fact that in these dislocations (not only of the thumb but also of the fingers) it is the glenoid ligament which is the mechanical obstacle to reduction. By freely exposing the joint I was able to see the glenoid ligament stretched over the head of the metacarpal bone.

Bradford.

DIABETES MELLITUS IN A CHILD, WITH COMA.

BY J. G. MCNAUGHTON, M.D., M.R.C.P. EDIN.

THE fact that diabetes mellitus in children, with rapid coma, is comparatively rare may make this case worthy of record.

I was called to see a girl, aged five years, on Jan. 21st, 1901, and obtained the following history. Wasting had been observed for only four weeks, and three weeks previously the mother had observed that the child was drinking large quantities of water. She would send her older sister for "drinks" during the night. At the same time she was passing more urine than usual. She complained of nothing else and played about as usual. No increase of appetite was observed. Three weeks before both ears discharged for one day, but there had been no discharge since. On examination on Jan. 21st the pulse was 116 and small; the temperature was 97·6° F. She was restless and difficult to rouse when spoken to. The skin was dry. The pupils were equal and there had been no twitching. She complained of no pain. The urine was straw-coloured and frothy, and on being tested it was found to contain sugar and albumin. The lungs and heart were normal.

On Jan. 22nd I was summoned at 7 A.M. The patient had vomited several times during the night. During the 24 hours she had passed over 20 ounces of urine. She was in great distress and complained of pain above the umbilicus. There was great dyspnœa, the respirations being 38 per minute. The lips, face generally, and limbs, especially the feet, were cyanosed; one tenth of a grain of codeia every three hours gave her some relief. The urine passed contained 6 per cent. of sugar and 3 per cent. of albumin. The patient was seen at 4 P.M.; there were even greater dyspnœa and cyanosis, and she was gradually passing into a comatose state. The coma gradually deepened and she died at 3 A.M. on the next day.

The progress of the case was apparently very rapid, no urgent mischief being suspected till two days before death. The parents are intelligent people and careful of their children. The family history was not good. The mother has had five children and the eldest, an imbecile, died when about nine years of age. An aunt of the mother died from diabetes, and a sister of the father died from the same disease when over 50 years of age.

No examination of the body was allowed. It is possible that there may have been some change in the base of the brain, but one could get no history of irritation of cranial nerves, the only fact elicited being the discharge from the ears.

On Feb. 21st the mother of the child sickened with influenza. When seen for the first time on the 22nd the temperature was 100·4° and the pulse was 98. On the same evening she became acutely maniacal and she died 36 hours later in the same state. This note may be of interest, taken in connexion with Dr. Howship Dickinson's Baillie lecture in THE LANCET of Feb. 2nd, p. 299.

ST. GEORGE'S HOSPITAL.

GLYCOSURIA DUE TO MORPHIA COMPLICATING A CASE OF FRACTURE OF THE PATELLA.

(Under the care of Mr. A. MARMADUKE SHEILD.)

THE importance of the fact that in some cases glycosuria appears as a result of the administration of morphia can hardly be over-estimated in connexion with the fact that morphia and the closely allied alkaloid codeia are prescribed more frequently perhaps for diabetes than is any other drug. The cases, however, in which this idiosyncrasy is observed are extremely few in number. In the case recorded below, although it was not definitely proved that the sugar was due to the morphia, yet it is very probable. For the notes of this case we are indebted to Mr. Charles R. Keyser, surgical registrar.

A man, aged 55 years, was admitted into St. George's Hospital on Nov. 3rd, 1900, under the care of Mr. Sheild. The history was as follows. Whilst waiting to catch a train the patient slipped and fell and on attempting to walk found that he was unable to do so. On admission to the hospital he was found to be suffering from a transverse fracture of the patella. The two fragments were separated about three-quarters of an inch and the knee-joint was much distended with blood. The upper fragment was a good deal larger than the lower. There was no head injury. Beyond the fact that he suffered from a chronic cough he was apparently in good health. The urine was normal.

On Nov. 5th Mr. Sheild opened the knee-joint by a median vertical incision and after thoroughly washing out the blood and clots brought the broken fragments into apposition by means of two wire sutures placed parallel to each other in the long axis of the bone. Two wires were used as the lower fragment was split longitudinally. The joint was again thoroughly flushed out, the skin wound was closed with sutures, and the limb was immobilised by means of a back splint and two side splints. A few days later the urine was again examined and a large amount of sugar was present. The patient had no other symptom of diabetes and it was only after some difficulty that any cause for the glycosuria was found. Finally, it was discovered that he had been taking morphia for upwards of 20 years to allay his cough. As there has been some doubt as to whether the sugar present in these cases is really sugar and not glycuronic acid Dr. G. A. Buckmaster, lecturer on physiology to St. George's Hospital, kindly examined the urine and gave the following report: "Total amount of urine for 24 hours = 1486 cubic centimetres. Deep orange colour which is due to pathological urobilin. Reaction neutral. Specific gravity 1035. It contains no sediment or smell. Froths readily. Contains sugar in quantity as determined by fermentation, but no glycuronic acid, acetone, oxybutyric or aceto-acetic acid. Total amount of urea = 31 grammes." This definitely showed therefore that the urine was not that of diabetes.

The wound in the knee healed quite satisfactorily, but for the first fortnight after the operation the mental condition of the patient was strange. He frequently tried to take off his splints and get out of bed, and whilst doing this he seemed quite dazed, and when told about it afterwards apparently had no knowledge of what he had been doing. He slept very badly and drugs such as trional and chloral were administered as required. The amount of sugar in the urine steadily decreased in amount and on Nov. 30th only a trace could be found, although urobilin was still present. On Dec. 4th, however, no sugar could be found in the urine. The knee was massaged and moved gently every day from Nov. 24th and by Dec. 2nd the patient was walking about the ward. On Dec. 12th, although he could walk quite well and could flex the knee nearly to a right angle, there was practically no union whatever between the fragments of the patella, the bone being entirely held in position by the wires. He was discharged from the hospital with strict injunctions to present himself frequently so that his condition might be observed. Unfortunately, he has never returned to the hospital, so that it has not been possible to determine whether the sugar is again present in the urine now that he has access to morphia, of which, presumably, he will avail himself to allay his cough which certainly was rather troublesome during his stay in the hospital.

Remarks by Mr. KEYSER.—The only references I have been able to find on this subject of glycosuria due to morphia are the following. In Allbutt's "System of Medicine," vol. iv., page 309, he says: "Glycosuria occurs after the administration of various drugs and poisons, more especially of morphia, chloral, opium, chloroform, and carbonic oxide. It is probable that the reducing substance in the urine is not dextrose but a compound of glycuronic acid." In Taylor's "Practice of Medicine," fifth edition, p. 851, it is stated that "the supposed occurrence of glycosuria after the administration of morphine, curare, and chloroform vapour is due to glycuronic acid." However, Mitchell Bruce in his "Materia Medica" says: "Morphine may produce sugar in the urine." In relation to these statements it is, therefore, interesting to know that it is possible for sugar as well as glycuronic acid to be produced by morphia, especially as the drug is constantly administered to diminish the amount of sugar in the urine in diabetes. The fact that sugar was only present after the operation may, I think, be explained in the following way. In the patient's ordinary condition of health his tissues were capable of disposing of the sugar-forming substances present as a result of morphia, but when the extra call on them was made they were unable to meet the double demand, and in consequence the fracture did not unite, although the skin wound healed by first intention, and sugar appeared in the urine. For permission to record the case I am indebted to Mr. Sheild.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THREE CASES ILLUSTRATING THE OPEN-AIR TREATMENT OF PERNICIOUS AND OTHER FORMS OF TOXIC ANÆMIA.

(Under the care of Dr. LAURENCE HUMPHRY.)

IT is now generally recognised that one of the most important factors in the etiology of various obscure morbid conditions of the blood is the presence in the circulation of toxins. These toxins may be absorbed from the alimentary canal or they may be taken up from some septic focus, such as an abscess, or they may even be formed by organisms present in the blood itself. Our chemical knowledge at present is hardly sufficient to enable us to identify in the blood the special toxin in any particular case, but we may reasonably look forward to this in the future. The value of dwelling in the open air in such conditions as these is well illustrated by the three cases Dr. Humphry has reported below. In the elaborate discussion at the Royal Medical and Chirurgical Society in 1899[1] on the open-air treatment of tuberculosis it was recognised by several speakers that the beneficial effect was not confined to the lungs, but was recognisable in tubercle occurring in other parts of the body. The improvement is probably to be attributed in great part to the increase in the appetite and in the capacity for sleep, which gives rise to a general increased power of resistance to morbid germs and their products.

CASE 1. *Pernicious anæmia with postero-lateral spinal sclerosis.*—A man, aged 53 years, married, was admitted into Addenbrooke's Hospital, Cambridge, on March 3rd, 1900. Early in 1899 he began to feel ill with loss of appetite, drowsiness, and weakness; he kept at work until about the end of the year when his gait began to be unsteady. In January, with increasing weakness, noises in the head, and difficulty in walking, he gave up work and attended at the hospital as an out-patient, but derived little benefit. On admission he appeared to be very ill; he had lost flesh and

[1] Transactions of the Royal Medical and Chirurgical Society, vol. lxxxiii.

was very anæmic, with a pale lemon tinge of the skin. The pulse was feeble and soft and the artery was slightly thickened; the heart sounds were feeble and muffled. Examination of the blood showed that the red cells were much altered in shape, numbering 1,685,000 per cubic millimetre; the white cells numbered 12,000 and the hæmoglobin amounted to 35 per cent. The urine was normal and of pale colour. The temperature oscillated between subnormal and slightly febrile. The patient's gait was ataxic; there was no absolute loss of power but great general weakness. Sensation was rather dull in the legs, with numbness and "pins-and-needles" in the fingers and toes. The knee-jerks were slightly exaggerated; there was no clonus; there was extensor response to plantar reflex. There was no loss of control over the sphincters. The pupil of the right eye reacted, the sight was good, and the fundus was normal; the sight of the left eye had been lost through accident. The digestion was fairly good. The teeth were ill-kept and the gums were swollen. The bowels were constipated. The abdominal viscera were not enlarged.

The patient was treated with rest in bed in the ward, a liberal diet, and small doses of strychnine. He improved slightly in strength, but after several weeks in spite of the administration of arsenic and iron his condition got worse, the anæmia increased, and the count of the red cells on April 6th was 1,200,000 per cubic millimetre, the hæmoglobin amounted to 25 per cent., and there were several nucleated red cells; the megalocytes and microcytes were about equal in number and formed about half the number of the red cells. In April he was given red marrow (five grains three times a day) and during the month the arsenic was increased to 10 minims of Fowler's solution three times a day. There was a slight increase in the number of red cells on April 26th, but early in May he got much worse and looked as if he was going to die, and his wife decided to take him home. It was obvious that during his stay in the ward he had steadily got worse and was much weaker, in spite of good nourishment, port wine, arsenic, and bone marrow. His wife was advised as they lived in the country and had a garden to let him remain out all day in the open air, and the drugs were continued in smaller doses, and good nourishment was to be given. By July he had greatly improved and his wife reported that since living in the open air his complexion had improved, he was gaining strength and appetite, the breathlessness on movement was less, and she thought that he would be soon able to travel in his bath-chair to the hospital. On August 14th he was brought up in a chair looking a great deal better, especially in colour; although still anæmic his skin looked healthier. The blood count was—red cells 2,320,000 per cubic millimetre and white cells 7000. Several films were stained but no nucleated red cells were found. The red corpuscles were of much better shape and size than in the previous counts. There was no obvious change in the nervous symptoms but muscular power was greatly improved. In November last, in reply to a letter, his wife said that he was not quite so well as he had been in the summer, but the weather had been bad and he had not been able to sit out.

CASE 2. *Toxic anæmia due to post-typhoid septicæmia.*—A young man, aged 20 years, single, was transferred to Dr. Humphry's care in the summer months suffering from profound anæmia after a very severe attack of typhoid fever with numerous complications followed by septicæmia. He appeared to be in the weakest possible state and he was wasted almost to a skeleton; his temperature was still febrile and oscillating and there were the remains of a sinus of a parotid abscess, but there was little discharge and there was nothing obvious elsewhere. The blood count on July 16th showed that the red cells numbered 2,842,700 per cubic millimetre and the white cells 20,000, and there was a large increase in the polymorphonuclear neutrophiles.

The patient lay in a lethargic state, half or quite asleep, with his eyelids half open. He could not turn himself in bed and looked a most piteous object. The septicæmia was evidently still going on, as shown by his temperature. On August 8th, as he was getting worse, he was given 10 cubic centimetres of antistreptococcic serum, having four doses in the course of a few days. This was followed by no apparent benefit, and at the end of the month he was drowsy, exhausted, and apparently dying. On Sept. 1st he was moved on to the balcony for night and day and the change in a few days was remarkable. His appetite soon became enormous. On the 10th he weighed 5 st. 5 lb. and on the 24th 6 st. 4 lb.—a gain of about a stone. On Oct. 3rd the red blood cells were found to number 4,368,000 per cubic millimetre. (N.B.—This patient had subsequently a severe relapse of his septicæmic state and died with pyæmic abscesses in his joints.)

CASE 3. *Hæmolytic anæmia, probably pernicious.*—A widow, aged 60 years, attended at the hospital as an out-patient in May, 1900. She had been failing in health and strength for nearly a year and was getting paler and breathless on exertion; she also occasionally had fainting attacks and vomiting. She was very pale, with a uniform lemon tinge of the skin and conjunctiva; there was plenty of subcutaneous fat; the mucous membrane was very anæmic. The heart sounds were feeble at the apex and base. There were no teeth in the lower jaw, but there were a few sound teeth in the upper jaw. The blood was of specific gravity 1036, the hæmoglobin was 34 per cent., the red cells numbered 792,000 per cubic millimetre, and the white cells 2900, and the colour index was 2·15. Poikilocytosis was well marked, three nucleated red cells being present in the film; there were more megalocytes than microcytes.

The patient was treated with arsenic and iron; she improved slightly and left off attending at the hospital. She got much worse in August and entered the hospital as an in-patient on Sept. 5th. She complained of great weakness, breathlessness, and indigestion. Her temperature oscillated between 96° and 100° F. and the pulse was soft, feeble, and regular. The urine was pale and scanty, but normal. On the 6th there was poikilocytosis; the red cells numbered 1,440,000 per cubic millimetre, and the white cells 2444. There was no hæmorrhage of the discs; the viscera were not enlarged. She was placed in bed in the ward and was given half an ounce of the glycerine extract of bone marrow twice a day and "admission diet." On the 14th she was much the same, the red cells being rather less (1,232,000 per cubic millimetre). She was placed on the balcony on the 13th, but at first she was losing weight and had several attacks of sickness and faintness and then, owing to work to be done to the roof of the balcony, she had to return to the ward. She was placed on arsenic again on the 24th, taking four minims three times a day. She complained that she had had to leave the balcony, as she slept better out of doors. She was put back on the balcony for night and day on Oct. 8th; she then weighed 8 st. 5 lb. On Sept. 29th the red cells were 1,480,000 per cubic millimetre. From Oct. 8th onwards her improvement was steady and well maintained, she slept well, and the appetite improved. On the 21st she weighed 8 st. 7¼ lb., having gained 2¼ lb. Her colour was less sallow and yellow and some fresh colour began to appear in her cheeks and lips. On the 28th she weighed 8 st. 10 lb., a total gain of 5 lb. On the 20th, the red cells numbered 3,600,000 per cubic millimetre and the white cells 4000; the hæmoglobin amounted to 70 per cent.; the red cells were of better shape and size. On Nov. 6th she was discharged from the hospital. She then weighed 9 st., a total gain of 9 lb.; she was looking well, with plenty of colour, the lemon tinge quite gone, and she expressed herself as quite well again after nearly two years' illness.

Remarks by Dr. HUMPHRY.—In the treatment of pulmonary consumption the fact has often been observed that amongst the numerous benefits derived from life in the open air there is a very decided increase in the number of the red cells of the blood. This fact should not be lost sight of and suggests a very material aid in the treatment of those severe forms of anæmia in which a great diminution in the number of red cells is a marked feature. The balconies at Addenbrooke's Hospital having been recently fitted up to accommodate patients the opportunity has been afforded of giving this mode of treatment a full trial; at the same time, owing to the work of preparing the walls, floor, &c., it was necessary from time to time to send the patients back into the wards, and in this way clinical experiments were made which were of some value.

The first case was admitted to the hospital before the balcony was ready for use, but the benefit which the patient derived from living in the open air after leaving the hospital was so marked that it was decided to give the plan a full trial on the next opportunity. This case was a well-marked example of pernicious anæmia with spinal symptoms. He was for many weeks thoroughly treated with rest in bed, liberal diet, arsenic, and bone

marrow, but he steadily got worse until he lived in the open air. The second case was one of profound toxic anæmia due to post-typhoid septicæmia. The rapid improvement in weight (nearly a stone) and the increase in the number of the red cells (nearly 2,000,000 per cubic millimetre in one month) were remarkable. The third case, again, was probably a toxic form of anæmia or pernicious anæmia. The patient after about five weeks in the open air appeared to be nearly well. The value of rest and good diet and of the administration of arsenic and probably bone marrow is of course well known, and the effect of rest on the blood in health and simple anæmia has been shown in very careful experiments by Dr. G. Oliver in his work on the blood and blood pressure. In the two cases of pernicious anæmia the treatment by rest, diet, and drugs was practically the same when in the wards as in the open air. The second case had no special drug treatment at either time.

The effect of living by day and by night in the open air upon the appetite, sleep, digestion, and, finally, upon the blood was very pronounced, and the rapidity of the improvement was also remarkable. The red cells not only considerably increased in number but in the cases of pernicious anæmia the shape of the cells was noticed to have materially improved. It was also noticed that the patients did better when they slept out than if they came back to the wards at night. The balconies are entirely open and face due west, with only a roof, and during the greater part of the year there were not even blinds to afford protection from the wind, weather, or sun. No ill-effects were noticed from wet, damp, fog, or wind, but occasionally the sun was too powerful. It is no doubt well known that what appear to be cures or improvements in this form of anæmia are often transitory and that relapse is to be expected; nevertheless, it is often not difficult to arrange for living and sleeping in the open air, and, at any rate, it may prove a gain if only in a sense of well-being and comfort, while in more favourable or earlier stages of the disease the severer symptoms may possibly be prevented.

I am indebted to Mr. Strangeways Pigg and to his assistants in the pathological laboratory for the careful blood examinations.

PATHOLOGICAL SOCIETY OF LONDON.

Immunity in Relation to the Pancreatic Ferments.—The Immediate Diagnosis of Rabies.—On a Proteolytic Enzyme in the Spleen.—The Fermentation of Glucose by Sanarelli's Bacillus Icteroides.—The Nature of the Indol-reacting Substance in Diphtheria.—The Identity of Achalme's Bacillus and the Bacillus Enteritidis Sporogenes (Klein).

A MEETING of this society was held on March 5th, at the Jenner Institute of Preventive Medicine, Mr. W. WATSON CHEYNE being in the chair.

Dr. GEORGE DEAN made a communication on Experiments on Immunity in Relation to the Pancreas and its Ferments. After reference to the resemblance between the ferments and the bacterial toxins a brief outline was given of the work previously done in connexion with ferments of animal, vegetable, and bacterial origin and their anti-ferments. Special attention was given to Hildebrandt's researches in connexion with emulsin, and Morgenroth's work in relation to rennin and anti-rennin. The latter formed the starting point of the experiments detailed. Animals were treated with gradually increasing doses of pancreatin with the view of ascertaining whether an increase in the anti-tryptic action of the blood-serum could be obtained. It was demonstrated that such an increase did occur, but that it was low compared with the case of the bacterial antitoxins. The animal body appeared to have the power of regulating the production of trypsin and anti-trypsin, an excess of the one being followed by a hypersecretion of the other.

Dr. A. MOORE made a communication on the Immediate Diagnosis of Rabies in Animals. Although the establishment of a rapid diagnosis in cases of suspected rabies was a matter of considerable importance in view of the treatment of persons bitten by such animals, yet the methods in vogue at present for arriving at this decision were all open to objection for the following reasons—viz., (1) the living animal was rarely available for observation of the characteristic symptoms; (2) the dead animal often presented macroscopically no really conclusive signs of the malady beyond the evidences in the stomach of its perverted appetite; whilst (3) the classical method of inoculation always involved a delay of at least two or three weeks and was frequently inapplicable owing to putrefaction of the material used for inoculation. The frequently advocated microscopical examination of the medulla oblongata had not been deemed worthy of general adoption. Recently van Gehuchten had drawn attention to a lesion which he considered to be absolutely pathognomonic of rabies. This consisted in a remarkable degeneration of the large conspicuous cells found in the ganglia of the cerebro-spinal nerves. A considerable number of these cells atrophied completely, their place being taken by small round cells and new-formation tissue, whilst those which persisted stained badly and presented a shrunken, wasted appearance, and in most instances a disappearance of their nuclei. These changes were most obvious in the ganglion found on the trunk of the vagus nerve close to its exit from the cranium and required no special mode of preparation to demonstrate them. The lantern slides and specimens exhibited represented sections of these ganglia taken from rabbits inoculated subdurally with the stock virus of the Jenner Institute. Van Gehuchten stated that the appearances described were found in all the rabid animals examined, being best marked in dogs, less pronounced in man, and least evident in rabbits, but highly characteristic in all. They were not found in animals not suffering from rabies.

Dr. S. G. HÉDIN and Mr. S. ROWLAND made a preliminary communication on the Presence of a Proteolytic Enzyme in the Spleen. The material on which the investigations had been made consisted (in the main) of the intracellular contents of the cells of the organs. (This material had been prepared by Mr. Rowland with the aid of special mechanical appliances devised for the purpose, whilst the search for enzymes had been conducted by Dr. Hédin.) In the first place it was tried whether such material would ferment its own albumin if allowed to stand at blood heat in the presence of an acid. The presence of proteolysis was sought for by determining the amount of nitrogen which was not precipitated by tannic acid before and after the expiration of certain times, the final products of the decomposition of albumin not being precipitated by tannic acid. In the case of the spleen it was found that this nitrogen regularly increased as time advanced. This increase was slight in alkaline and neutral solutions, but considerable in slightly acid solutions. The spleen juice itself always had an acid reaction and sometimes it was so strongly acid that the addition of an acid did not increase the acid reaction. Control experiments were made so as to ascertain whether the boiled juice digested with an acid gave any increase of the nitrogen not precipitable with tannic acid, and the same result was always found in the boiled and digested juice as with the fresh juice. A table of the results was exhibited showing the quantities of nitrogen before and after digestion in presence of acetic acid, sodium carbonate, lactic acid, hydrochloric acid, neutralised solutions, and also showing the results at various times (16, 22, 40, and 90 hours). The researches demonstrated that the albumin of the spleen juice was digested and that this action took place especially in an acid solution; and since there was no difference in the amount of albumin in the boiled and the unboiled juice it was concluded that the changes were due to an enzyme which acted most readily in acid solution. The effect of spleen juice on added albumins was also investigated. Thus a boiled portion of spleen juice was added to a portion that had not been boiled, and the altered amount of albumin was found to be larger than without the addition of the boiled portion. The effect was the same if some blood was added to the spleen juice. The most striking results ensued from the action of the spleen juice on fibrin. If 200 grammes of wet fibrin were added to 450 grammes of spleen juice it was practically all dissolved in about 16 hours. In this case the amount of nitrogen not precipitable by tannic acid without and with the added fibrin was found to be in the former case 34 cubic centimetres and in the latter 57·4 cubic centimetres. It was concluded from the various experiments made that the spleen contained an active proteolytic enzyme which acted most readily in acid solutions, and this substance Dr. Hédin and Mr. Rowland proposed to designate "lienase."

Dr. A. HARDIN made a communication on the Fermentation of Glucose by Sanarelli's Bacillus Icteroides. The culture employed was received from Kral and showed all the usual cultural tests of this organism. The organism was cultivated in a 1 per cent. solution of Witte's peptone, containing 20 grains of pure glucose and 10 grains of chalk, under anaerobic conditions, in an atmosphere of nitrogen. At the end of four weeks the evolution of gas had ceased and the products were examined and found to be the following: lactic acid, 49·2 per cent.; acetic acid, 15·9 per cent.; alcohol, 10·8 per cent.; succinic acid, 3·3 per cent.; formic acid, 1·5 per cent.; and carbon dioxide, 16·0 per cent. The lactic acid was lævo-rotatory and consisted of about 10 per cent. of inactive and 90 per cent of active acid. The gas consisted of carbonic acid and hydrogen. After allowing for the volume of carbonic acid produced by the action of acids on the chalk it was found that the carbonic acid and hydrogen had been formed from the sugar very nearly in the ratio 1 : 1. These products were precisely similar both qualitatively and quantitatively to those formed by the bacillus coli communis under the same conditions. This was in agreement with the observations of Cushing on the gas and acid production of this organism.

Dr. R. T. HEWLETT made a communication on the Nature of the Indol-reacting Substance present in Diphtheria Cultures. He had, he said, at a previous meeting of the Pathological Society of London drawn attention to the fact that cultures of the diphtheria and of the pseudo-diphtheria (Hoffmann) bacillus yielded a pink colour when treated with a nitrite and acid which resembled the colour given when traces of indol were present. The substance, however, was not indol, as it was non-volatile. Further experiments had been made to isolate and determine the nature of this substance, and these had proved it to be skatolcarboxylic acid. This compound was non-volatile, easily soluble in alcohol and ether, and feebly so in water. With nitric acid and a nitrite a reddish pigment was formed which was freely soluble in acetic ether. With hydrochloric acid and perchloride of iron it gave a cherry-red colour which was taken up by amyl alcohol. With hydrochloric acid and chloride of lime it gave a reddish colour, this pigment being likewise soluble in amyl alcohol. The substance isolated from the diphtheria cultures conformed to all these reactions. The fact that both the diphtheria bacillus and the pseudo-diphtheria bacillus formed skatolcarboxylic acid might be regarded as additional evidence of the relationship between these two organisms.

Dr. HEWLETT also made a communication (illustrated by cultures and specimens) on the Probable Identity of Achalme's Bacillus of Acute Rheumatism and the Bacillus Enteritidis Sporogenes of Klein. On one occasion he (Dr. Hewlett) had isolated from a case of acute rheumatism a bacillus which conformed in all particulars to that described by Achalme.[1] He was also struck with the resemblance between the latter organism and the bacillus enteritidis sporogenes of Klein. Having been courteously furnished with cultures of Achalme's bacillus by M. Achalme himself Dr. Hewlett had compared the two organisms and was unable to distinguish any marked difference between them. Both were anaerobic, anthrax-like bacilli, curdling milk in a peculiar way, forming spores only under certain but identical conditions (namely, on gelatin, but not on agar), forming gas and liquefying gelatin, and having a marked and distinctive pathogenic action upon guinea-pigs. Morphologically, culturally, and in pathogenic action the two organisms seemed to him (Dr. Hewlett) to be identical.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

Proposed Epileptic Colony.—Murder the Result of Pure Homicidal Impulse.—Death of the late Queen.—The Chemistry of Nerve Degeneration.—Morbid Changes in Dementia

A GENERAL meeting of the members of this association was held on Feb. 14th. at the London County Asylum, Claybury, Essex, Dr. FLETCHER BEACH, the President, being in the chair.

Mr. W. C. CLIFFORD SMITH, engineer to the Asylums Committee of the London County Council, read a paper on, and exhibited the plans of, the Proposed Epileptic Colony to be Built on the Horton Estate, Epsom, the building having been designed by Mr. Clifford Smith on the lines suggested by Mr. G. J. Cooper, L.C.C., in his report upon "A Scheme for the Establishment of an Epileptic Colony."—In the discussion which ensued Dr. J. WIGLESWORTH described a visit which he paid to Germany last spring to inquire into the segregation treatment of the insane there. As a result of the visit he recommended the adoption of the system for a Lancashire asylum which was then being projected. The present suggestion was that villas should be for both epileptics and imbeciles. The villa system had attained great development in Germany, particularly in the newer asylums, where a colony was established in connexion with the main buildings, or the asylum consisted entirely of such villas, accommodating from 40 to 50 patients each. He was much impressed by the comfort and general home-like surroundings, and he thought future developments should be on those lines in preference to the colossal buildings of which those at Claybury formed such a magnificent example. Much credit was due to Mr. Clifford Smith for his efforts, as he was one of the pioneers of the movement in this country. He understood it was suggested that there should be a large central dining hall, to which the residents of the surrounding villas should resort for their meals, or at least the hot ones. He (Dr. Wiglesworth) was in favour of the opposite plan—namely, that the meals should be served in the separate residences—then the conditions came much nearer those of home life. In Germany the dinners were sent to the residences on wagons from a central cooking establishment, and they succeeded in getting all the meals served in a reasonable time. The food was practically surrounded by a hot-water jacket. With regard to heating, in many of the German asylums there was a small simple boiler for hot water, in addition to open fireplaces, and he thought that on the whole such a plan was the best for warming the dormitories at night. He thought that the patients in any one villa should number from 36 to 40. For these there should be four attendants, and for the supervision of the attendants he advocated the tell-tale clock system.—Dr. A. R. URQUHART agreed that there should be four attendants to each villa, and that the number of inmates of any one villa should not exceed 40. With reference to the question of heating, in two projected asylums for Edinburgh and Aberdeen it was intended to supply steam from a central boiler. That plan had been found practicable for an American town of 30,000 inhabitants which he had visited, where the houses of the better classes were provided with steam from a central station, at prices which varied with the house rentals. The extreme distance to which the steam was supplied was about two miles. For Aberdeen he suggested a saddle boiler, like an ordinary conservatory boiler, for each villa, to be regulated by the scullery attendant. In his own house some years ago he had his kitchen boiler connected with a system of radiators, and had now the satisfaction of knowing that the heat was not passing up the chimney but was being distributed to various parts of the house. Recently a paper was read before the Institution of Civil Engineers by Mr. Roberton, in which he advocated a considerable extension of the system, claiming that by means of two specially-designed zig-zag boilers in the kitchen any ordinary mansion could be well heated. Reference had been made to the German method of conveying the meals in specially constructed vessels, but what kind of meals were they? The last such meal he saw conveyed round consisted of vegetable soup with a herring floating in it. Such meals would scarcely do for English institutions. In Hartford, Conn., U.S.A., where there were a number of villas for people of the higher social grades, dinners were sent round by means of an underground channel, and with considerable success.—Mr. H. F. HAYES NEWINGTON thought the villa system was applicable to other than epileptic patients. With regard to the food, the right object to aim at was the approximation of the conditions to those in home life, but he hoped that a more suitable name would be found for the buildings of the colony than "villa." As to heating the institution, in a new asylum in Sussex the intention was to heat the villas by means of open fire-places as far as possible, though in an epileptic colony there was the difficulty that patients might fall into the fire. In the asylum to which he had referred provision had been made underneath for a heating chamber for use if necessary. As to the arrangements for supplying food, it was decidedly institutional and not conducive to domesticity to send the patients to take their meals together in a large

dining-hall. That, however, could be overcome by supplying the dinners to the villas in carts from a central establishment, as was to be done in Glamorgan. In that county three villas were being built, and in respect of one of them the cart system would be adopted. For the other two there would be a separate kitchen in each, and they hoped to be able to get a good housewife who would be able to see to the necessities of the patients and who could so regulate the food as to effect a saving.—Dr. ROBERT JONES (Claybury) pointed out that the plans exhibited by Mr. Clifford Smith did not provide for a chapel for the patients. The epileptic was the only person who possessed the perfervidity of temperament which made him feel most comfortable in chapel. Would it not therefore be better that the patient should have his *summun bonum*, a chapel, the place which was to him a veritable haven of rest?—Mr. CLIFFORD SMITH briefly replied. He could only look at the religious feeling of the patient from an engineering standpoint. If the epileptic required a chapel the engineer would say, let him have it. The question of heating was a vexed one, and it had been his lot to deal with every type of heating which had been devised—high-pressure steam, low-pressure steam, high-pressure water, low-pressure water, and electric heating. Many grievous ills were laid by some at the entrance to the door of the system of heating, such as tuberculosis and colitis. By carrying out the scheme he had outlined they could have a system of heating such as was common in the houses of the people, and they could have the opportunity of ascertaining whether the same evils accrued from that system as were alleged against the other methods. As to food, it had been admitted that it was good to go out to dinner every day, and that was what the epileptics would do under that scheme. He was not quite sure what arrangements could be made for the staff, but if they would only walk to the central dining-hall they could be sure of a substantial cooked meal.

Dr. WIGLESWORTH read a paper entitled a Case of Murder the Result of Pure Homicidal Impulse. The murder was committed in a Lancashire asylum by a female inmate in obedience to a sudden homicidal impulse, the patient never having shown while there any such tendency. Subsequent investigation, however, showed that her behaviour at other institutions might have been so construed had the full facts been known.—Dr. L. A. WEATHERLY related the circumstances of a murder near Bristol committed by a lad, aged 17 years, the victim being a farmer who gave the lad a "lift" in his cart towards his home and was stabbed to death while driving. It was shown that the demeanour and character of the lad had changed from the time he received an injury to his kidney in a tram accident. Dr. Weatherley proved eccentric behaviour from that date, but the prison surgeon said he found nothing mentally abnormal. The result was that the boy was adjudged guilty. On strong representations being made on the subject the sentence was altered, but only to one of penal servitude.—Dr. BOYLE spoke of a murder case in Nottingham in which he would have to give evidence. The alleged perpetrator of the crime denied all knowledge of the act, insisting that he could not remember anything beyond a certain time, but he gave a very cogent history of his doings up to that time. The first thing he said he remembered afterwards was the attempt of the police surgeon to "stomach-pump" him. There was no family history of epilepsy; the father died from apoplexy, and one sister died insane. The patient himself had sunstroke some years ago. He asked whether it was possible for a non-epileptic to lose consciousness for several hours, to commit a crime during the period, and then to regain normal mental control. —Dr. R. H. NOOTT suggested that in a few days the amnesia might pass off and then careful questioning might bring out a motive for the crime. — Dr. MORRISON related the case of a man with occasional homicidal impulse who had managed to conceal it owing to his fear of being placed in an asylum, but one day on being found in a typical epileptiform attack he was closely questioned, and the facts were then admitted. He appeared to have stuck pins all over his body during unconsciousness, and to have repeatedly stabbed the site of an inguinal hernia. He suggested that Dr. Boyle's case might be one of *petit mal*.—Dr. ROBERT JONES said that the patient who formed the subject of Dr. Wiglesworth's paper was twice in Claybury Asylum, once for six weeks and again for six months, but never showed any homicidal tendency. On the certificate for the second admission, however, it was stated that in another asylum she had said that she would "kill somebody."—Dr. WIGLESWORTH briefly replied. In regard to Dr. Weatherley's case he was not surprised at the decision of the jury seeing that the medical experts differed. He was inclined to regard Dr. Boyle's case as one of unconscious cerebration. He quite believed there were such cases.

The PRESIDENT, in opening the proceedings of the Pathological Section, referred in suitable terms to the nation's loss in the death of the late Queen, and a resolution of sympathy and condolence with the King was approved and ordered to be forwarded to the proper quarter.

Dr. W. D. HALLIBURTON, F.R.S., gave an address (in the absence, through illness, of Dr. F. W. MOTT, F.R.S., pathologist to the asylum) on the Chemistry of Nerve Degeneration. The address was illustrated by numerous lantern slides.

Dr. JOSEPH BOLTON read a paper, supported by many lantern views, on Morbid Changes in Dementia.—In the discussion which followed the PRESIDENT, Dr. WIGLESWORTH, and Dr. ROBERT JONES joined.—Dr. BOLTON'S reply closed the proceedings.

WEST LONDON MEDICO CHIRURGICAL SOCIETY.—A clinical meeting of the above society was held at the society's rooms on March 1st, Dr. F. F. Schacht, the President, being in the chair.—Mr. G. L. Cheatle showed a boy on whom he had performed a new operation for Prominent Auricle. This operation was based on the principle that the antihelix was the part in excess causing the deformity, and the tissues were transfixed, a large, somewhat irregular, crescentic piece of the antihelix was removed, as was a small portion of the lower border of the helix. The result was very satisfactory, although the ears were not quite symmetrical, but the experience gained from this case would enable the operation to be performed more successfully in the future.—Dr. J. Barry Ball, Dr. Seymour Taylor, and Dr. Peyton discussed the case.—Dr. Ball read the report of the Microscopic Investigation of a Small Growth, probably an Endothelioma, removed from inside the ala nasi of a young woman.—Dr. Ball read notes of a case of Tuberculosis of the Skin and Mucous Membranes. The patient was shown at a meeting of the society last June. She was a woman, 22 years of age, who had extensive lesions of the skin, as well as of the gums, the palate, the pharynx, and the larynx. There was some difference of opinion at the time, but it was generally admitted that the condition resembled lupus. However, some maintained that the skin lesions were most probably syphilitic, and it was suggested that a thorough mercurial course would be beneficial. The patient, was, therefore, treated with mercury internally and as an inunction. During this period the condition of the mucous membranes improved, but there was no change in the skin lesions. The mercury was then given up and the lesions were treated by excision, cautery, or curetting. She rapidly improved and was on the point of leaving the hospital when she was seized with an attack of cerebral meningitis from which she died. The diagnosis of meningitis was confirmed by post-mortem examination, and Dr. Ball had no doubt that all the lesions from which she suffered were tuberculous in character.—Mr. Keetley and Dr. H. G. O. Wharry made some remarks.—Dr. Seymour Taylor showed a case of atrophy of the short muscles of the right hand in a case of tabes dorsalis. The patient had well-developed tabes, but in addition he had marked wasting of the short muscles of the right hand, which showed all the electrical reactions of degeneration. The left hand was not attacked. This, Dr. Taylor argued, proved that the patient had some local involvement of the cells in the anterior cornua of the cord supplying that particular group of muscles, this sclerosis having spread from the posterior external columns of the same side; it could not be peripheral in origin, as sensation had not been lost. He had had syphilis and had been treated for it, but with no amelioration of the symptoms.—Dr. A. Whitfield showed a male patient, aged 28 years, suffering from Neuro-fibromatosis or von Recklinghausen's disease. He was well up to nine years of age, after which these tumours appeared and gradually increased in number. They varied in size from that of a pin's head to that of a large hazel nut, were soft, normal or reddish brown in colour, adherent to the skin, and were most numerous on the trunk, then on the arms;

there were but a few on the legs. He also had a large semi-fluid swelling of the left cheek. There were no signs of myxœdema, but he had a very small thyroid. Microscopically a section of one of the tumours showed a few nerve fibres. The tumours were not painful or tender.—Mr. A. S. Grant showed (for Dr. P. S. Abraham): (1) A case of Pityriasis Rosea of Gibert; and (2) a case of Leucoderma and Melanoderma, with pruritic eczema from scabies, acne, and tertiary ulcers on the legs, the interest of the case consisting in the multiplicity of skin troubles.—Mr. Bidwell showed a case of Carcinoma of the Transverse Colon treated by excision, followed by ileo-sigmoidostomy. The patient was a man, aged 50 years, who had had attacks of abdominal pains for three years. When examined he had a long sausage-shaped tumour of some three or four inches in the left hypochondriac region. There was no intestinal obstruction. The patient refused operation, but about three months later an abscess burst near the umbilicus, another near the left inguinal region, and a third beneath the ribs on the left side. They continued to discharge pus and fæcal matter. On Dec. 20th, 1900, he was operated upon; the sinuses were slit up and scraped; the sinus under the ribs was followed up and it led to a perforation in the transverse colon, beyond which was a large growth. This was drawn outside the wound and the mesentery was tied in segments. A ligature was placed around the colon, one inch above and below the growths, and tied tightly. The abdominal wound was closed as much as possible. Three days afterwards the growth was excised, the ligature around the bowel was cut through, and an artificial anus was established. His general condition rapidly improved and on Jan. 20th the abdomen was reopened and the lower end of the ileum was united to the sigmoid by a lateral anastomosis. Three days afterwards the patient had a normal motion. As fæces still passed as well by the artificial anus the abdomen was reopened a fortnight later and the portion of intestine between the anastomosis and the cæcum was occluded. Since this the patient had put on flesh and had had a normal motion daily, although he had only about six inches of large intestine. Mr. Bidwell thought this method far safer than an end-to-end anastomosis, as there was not so great a strain on the sutures from semi-solid contents of the large intestine.—Dr. E. A. Saunders and Mr. McAdam Eccles discussed the case.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Feb. 19th, Dr. William Ewart, the President, being in the chair.—The President, in speaking of the Formaldehyde Treatment for Phthisis at Davos, described the remarkable improvement which had occurred in one of his patients whom he had injected on Jan. 12th, the first instance of a complete course of this treatment in the Alps. The case was that of a young man with acute asthenic catarrhal tuberculosis developing after the occurrence in Davos of a second profuse and almost fatal hæmoptysis. Before making the first injection the chances of recovery had appeared to him to be almost hopeless. Dr. F. Buol, who had continued the treatment, now reported the patient able to sit up and to take strong food, the temperature was normal instead of hectic, and the profuse, heavy, purulent expectoration had changed to a lighter muco-pus and its bulk diminished more than one third. The case illustrated the inadequacy of mere climatic treatment for the control of severe acute pulmonary tuberculosis, and the advantage which was likely to be gained when the formaldehyde treatment could be carried out with the additional help of the best climatic influences.—The President also exhibited two cases now under treatment at St. George's Hospital not quite so severe. Both had improved considerably; in one of them the bacilli were no longer found.—Mr. J. Foster Palmer made a further communication concerning an Organism passed from the Urethra of a Male Patient, which he had exhibited at a former meeting. Further investigation had shown the organism to be the larva of Homolomyia Scalaris, a small species of house fly. These larvæ, Mr. Palmer remarked, had been found in the rectum, but their presence in the urethra was exceedingly rare, not more than some 30 cases having been recorded since the time of Ambrose Paré, who was the first to describe the condition in 1582. Mr. Palmer's patient was present at the meeting, but showed no symptoms beyond some thickening in the penile portion of the urethra.—Mr. F. C. Abbott read a paper on Spinal Curvature and Physical Exercises. He dwelt on the inadequacy and failure of past lines of treatment and the disgrace that they should allow a mere temporary weakness to leave them such a legacy of cripples. Nor was the spinal deformity the only bad result; the effect on the chest was almost more important through leaving diminished resistance and increased liability to chest disease. Ordinary gymnasia run on purely hygienic lines were not sufficient and might do harm, as unless the exercises were well devised and controlled the stronger muscles must win and increase the deformity. After describing his own experience in the physical exercise department at St. Thomas's Hospital, and analysing the cases there treated, Mr. Abbott classified the cases according to prognosis into the three following groups. 1. Those in which the spine could be entirely straightened by the voluntary efforts of the patient alone. These cases rapidly improved, could take strong exercises from the first, and could easily be taught suitable "free standing" exercises for home use. 2. Those in which the deformity could not be obliterated by any effort on the patient's part alone, but could be made to disappear on suspension in a suitable position, and in bad cases by moulding as well. These were the cases true Swedish exercises did most for, while home exercises and mere free standing movements failed and might do harm During resistance movements well carried out even severe curves which neither the patient alone by her muscles nor an assistant alone by mere moulding or pressure could correct might be seen to straighten. Massage in these bad yet still hopeful cases was most useful. 3. Those in which permanent bony and ligamentous changes prevented any correction of the deformity. Forcible and strong exercises could only increase the deformity in these cases owing to the great advantage at which the muscles in the wrong side were acting. In these cases they should aim only at general muscular improvement and then fit a light spinal support. Mr. Abbott pointed out that the spinal muscles in these cases were not the only weak ones, but that weak abdominal muscles in such patients were often the cause of constipation, moveable kidney, &c., while a few patients were on the high road to general enteroptosis. For all these associated medical conditions and for increasing the chest capacity and range of movement the exercises produced really brilliant results. The importance of taking a correct fundamental position was insisted upon and the different strengths of any exercise according to the position taken were pointed out. The movements used were divided into (1) active, used as "free standing" movements without any help both as "changing position" and "fixed position" movements, without any "holdings"; (2) passive, used as general respiratory passive movements, as local passive movements, or massage, and as "mouldings," these last being of little importance except when combined with active movements; and (3) resistance, used both as "active-passive" and "passive-active." No mechanical contrivance could equal this graduated resistance of a skilled attendant, graduated as to time, strength, and point of application. Typical cases of the various deformities were shown, and the effects produced by the various main groups of exercises were demonstrated on them.—A discussion followed in which Dr. Charles Ewart, who described a method of treatment lately adopted in Paris and associated with the name of M. Lannelongue, Dr. J. Blumfeld, Mr. R. L. Norman, Mr. D. Vinrace, and Mr. R. Roche took part.—Dr. C. J. Harrison subsequently made a communication on the subject of Acute Rheumatism in Childhood.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The fourth meeting of the session was held on Feb. 20th at the Guildhall, Windsor, Mr. W. B. Holderness, J.P., the President, being in the chair.—The President opened the meeting with a few words touching the lamented death of Her late Majesty Queen Victoria, and embodied in a resolution, which was unanimously carried, the profound grief of the members of the society at the sad event and their sympathy with His Majesty King Edward VII.—Dr. W. F. Lloyd showed a specimen of an Ovum with Imperfect Development of the Decidua.—Mr. R. H. Paramore showed (by kind permission of Dr. W. A. Ellison) a specimen of Aortic Aneurysm from a man, aged 56 years. The aortic valves were rigid and heaped up with calcareous deposit.—Dr. E. B. Hulbert showed (by kind permission of Mr. J. R. Lunn of St. Marylebone Infirmary) the following: 1. An excised Bursa Patellæ showing old and recent inflammatory changes. 2. Specimens of Tuberculous Kidney and Bladder from a woman, aged 53 years. The right kidney was much atrophied and contained several caseous masses. 3. Two Photographs of a case of Elephantiasis of the Leg in a man, aged 70 years, formerly resident in the tropics.—

Dr. C. R. Elgood showed a specimen of a Dissecting Aneurysm of the Aorta from a gouty painter, aged 49 years. The aortic valves were sound. He also showed, (1) a case of Muscular Development after Sandow's Exercises; (2) a case of Ulceration of the Epiglottis; and (3) a woman whose Urine contained an abundant Deposit of Fat.—The adjourned discussion upon the Effect of Severe Athletic Exercise in the Young was resumed by Dr. M. S. Pembrey who said that the dyspnœa of exertion was not due to an accumulation of carbonic acid gas in the blood but was of cardiac origin and an effect of compensation. Rapid respiration assisted the flow of blood from the right to the left side of the heart. Alluding to "second wind," he believed that this was entirely a question of compensation between the heart and the respiratory pump. An increase of blood-pressure occurred during exercise—often reaching 40 millimetres of mercury. As evidence of heart strain caused by exercise taken by boys out of training he instanced two cases of dilatation of the right side of the heart after a hard bicycle ride. A rise of temperature also occurred during exercise; this was always apparent when the temperature was taken in the rectum or urine instead of in the mouth. The rectal temperature during exercise rose to 100° or 101° F., without any bad result. After severe exercise, and especially if the subject was unable to compensate, the rise was higher. In his opinion there was no doubt that severe muscular exercise was bad for the young, for there was often no time for efficient compensation. It was for this reason that training should be gradual and was so necessary a preliminary to a hard race.—Sir W. H. Broadbent agreed that the dyspnœa of exertion was cardiac. He had never accepted the chemical theory, for the worst dyspnœa occurred before there was time for the blood to become charged with carbonic acid gas. With regard to "second wind," the first effects of dyspnœa arose from the too rapid forcing of blood into the right heart from pressure on the veins by the muscles, the respiratory pump being unable to effect its removal sufficiently rapidly. The second wind came when the right heart had unloaded and redistribution of blood had taken place, this being helped by relaxation of the arterioles. Alluding to cardiac overstrain he laid stress on the importance of high arterial tension, and alluding to the great differences found in arterial tension among children he said that he had seen the worst dilatation of the left ventricle in high tension cases. In everyone there existed a line beyond which exercise was injurious, and as indications when that line had been reached he mentioned that after the exertion the dyspnœa continued, the heart failed to subside, and sleep was lost. He had seen a good deal of damage done to the heart mostly when exercise had been taken by persons when they were in bad health. He thought that when a murmur was traceable to an attack of rheumatic fever then exercises might be properly curtailed, but this did not hold in the case of a murmur in the pulmonary area, which disappeared on taking a deep breath and was due to an inadequate cushion of lung over the conus arteriosus. He had also learnt to disregard the importance of a tricuspid murmur which was audible in the erect but not in the supine position.—Surgeon-General Cayley said that among the more immediate effects of severe climbing exercise in the mountainous regions of hot countries he had noticed a temporary indisposition occurring in those fresh to the work. It soon, however, passed away, and was, he considered, probably the effect of a feverish condition. So, too, the "heat fever" observed in hot climates and which affected new-comers only. This, he thought, was induced by severe exercise and exposure to heat in those unaccustomed to the climate. In his experience he had found that irritable, nervous hearts were apt to fail sooner than those with more steady action.—The discussion was continued by Mr. H. E. Bruce Porter and Mr. E. W. Adams.—Dr. E. S. Norris briefly replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 1st, Dr. Gordon Black, the President, being in the chair.—Dr. A. Mantle (Halifax) read a paper entitled "Remarks upon Some Forms of Vaso-motor Disturbances, including Raynaud's Disease." He said that he wished the paper to be understood as a preliminary contribution to a subject which he had been investigating at the Royal Halifax Infirmary. After recalling the ordinary symptoms observable in the extremities in Raynaud's disease, which, he remarked, were frequently overlooked except when the extreme condition of gangrene was developing or was present, he dwelt upon the changes occurring in the brain which he believed to be of vaso-motor origin. Migraine was a common symptom in a large proportion of the cases. In a considerable number epileptic attacks occurred—a single attack or more at varying intervals. In the insane as well as in the epileptic vaso-motor disturbances of the circulation were observed. Palpitation was a very common symptom and angina vaso-motoria was cited as seen occasionally. Arterial tension in the majority of cases was minus and a varying degree of dilatation of the heart was noticeable. Dr. Mantle had only seen one case of hæmoglobinuria, and this was in a patient with high arterial tension who was a great meat-eater. He thought it comparatively rare and, as in hæmorrhage from the nose, uterus, or bowel, that it was associated with a plus blood-pressure These patients usually expressed themselves as feeling better after the loss of blood. Gastric cases were referred to in which food excited a feeling of pain and coldness of the extremities and body. These cases were not seen in the anæmic condition in which gastric disturbance was most frequent. Pains of a colicky character of varying duration occurring in the abdomen were also referred to. There was always a sad and anxious expression of countenance in all of these cases of vaso-motor disturbance. In some, particularly in the female sex, he had observed an enlargement of the thyroid gland, accompanied or not with proptosis, generally bilateral but sometimes unilateral. In others proptosis existed alone. These cases were quite distinct from Graves's disease and had no tachycardia and as far as he knew were undescribed. The symptoms were suggestive of a thyroid origin. In many there were changes in the nails of the fingers which were not only friable and malformed, but might have white or darker scars on them. The skin was sometimes bronzed or the condition of scleroderma was noticeable. Ophthalmoscopically in the cold stage he had observed contraction of the retinal arteries with dilatation of the veins. Dr. Samuel Lodge had noticed changes in the field of vision in several of his cases. Shock by lightning and, in the case of a soldier returned from South Africa, sunstroke had been the exciting cause in two of his cases. With the aid of lantern slides Dr. Mantle showed the chief points which he wished to call attention to in his cases and stated that he found suprarenal extract most helpful in their treatment, probably by raising the blood-pressure.—The President, Dr. Gordon Sharp, Dr. E. W. Selby, Dr. J. Kerr, Dr. T. W. Griffith, and Dr. H. J. Campbell joined in the discussion and Dr. Mantle replied.—Dr. W. Edgecombe (Harrogate) described a case of Secondary Anæmia due to repeated slight loss of blood from the nose, continuing over a period of 12 years, which finally presented all the symptoms of pernicious anæmia.—The President, Dr. S. Lodge, jun., Dr. A. G. Barrs, and Dr. E. F. Trevelyan took part in the discussion.—Mr. H. Littlewood showed a patient whose thigh had been amputated under an intra-spinal injection of cocaine.—Mr. B. G. A. Moynihan showed a patient after cholecystectomy for fistula between the cystic duct and the duodenum, the result of a calculus impacted in the termination of the cystic duct.—Other cases and specimens were shown by Dr. J. E. Richards (Huddersfield), Dr. T. Churton, Dr. A. Christy Wilson (Doncaster), Dr. Godfrey Carter (Sheffield), Dr. William Fearnley (Harrogate), Dr. J. Allan, Mr. A. L. Whitehead, Mr. E. Ward, Dr. J. B. Hellier, Dr. T. W. Griffith, Mr. Lawford Knaggs, and Dr. E. F. Trevelyan.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Feb. 15th at Liverpool, Dr. T. B. Grimsdale, the President, being in the chair.—Dr. J. E. Gemmell (Liverpool) showed a Solid Ovarian Tumour weighing three and a half pounds which he had removed by abdominal section from a woman, aged 30 years. The patient had ascites and symptoms of twisted pedicle. The tumour reached as high as the umbilicus and a sense of ballottement was elicited on vaginal examination. The tumour was solid, hard, yet boggy in consistence, smooth on the surface and furrowed, with large veins coursing over it. On section the upper portion of the growth was firm, hard, and typically fibroid in character, the fibrous tissue being arranged in the usual concentric fashion; in other portions the tumour was softer and injected with blood due to the strangulation of the twisted pedicle. The microscopical sections of the tumour showed it to be a fibroma. Two small fibroids were also present in the uterus and were enucleated. The left ovary was normal.—Dr. Gemmell also showed a specimen of Bilateral Surface

Papilloma. The growths covered the ovaries and were cauliflower-like in appearance, of a salmon pink colour, mainly pediculated with thin slender pedicles, a few only being sessile. Microscopically the papillary projections consisted of a stroma with numerous cells and blood-vessels covered with columnar epithelium. The growths were removed by abdominal section from a patient, aged 32 years. There was no ascites and no secondary deposits existed.—Mr. Rushton Parker (Liverpool) showed a large Fibro-cystic Tumour of the Uterus weighing 23 pounds, removed by abdominal section from a woman, aged 43 years. A serous cyst of doubtful origin was also found in the left side of the pelvis. The patient progressed favourably until the ninth day when she developed tetanus, from which she died on the following day. Anti-tetanic serum was used in vain.—Dr. W. Walter (Manchester) showed a Uterus removed by vaginal hysterectomy from a patient, aged 45 years, for an epithelioma of the posterior cervical lip.—Dr. Arthur Wallace (Liverpool) related a case of Perforating Laceration of the Cervix Uteri. The patient was a young married woman with a history of missed abortion. The cervix was of unusual length and lay curled up under the bulging anterior wall of the corpus uteri. The cervix was drawn into its proper axis with a vulsellum and a laminaria tent was inserted. Some hours afterwards the tent was expelled and following it a carneous mole, the passage of the latter being accompanied with unusual pain. On examination next day the cervix was found to be undilated, but a large opening was found behind the os large enough to admit two fingers. The opening extended from the os internum through the posterior cervical wall into the vagina, leaving a portion of normal cervix both behind and in front of the opening. The uterus was still acutely anteflexed. Dr. Wallace suggested that the laceration was probably due to the resistance offered to the passage of the mole by the long acutely flexed cervix. The peritoneum was not involved.—Mr. R. Favell (Sheffield) reported a case of Cæsarean Section for Obstruction of Labour by a Dermoid Ovarian Tumour. After the uterine wound was sutured the tumour was raised from the pelvis and removed. The patient made an excellent recovery.—Dr. H. Briggs (Liverpool) exhibited a specimen of Sarcoma of the Uterus.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 19th, Mr. F. Farrow, the President, being in the chair.—Dr. W. H. Horrocks read notes on a case of Stiff Knee-joint treated by Local Hot-air Baths. The case was one in which treatment of a fractured thigh had been followed by great limitation of the movements of the right knee. The Tallerman apparatus was used and the patient received in all about 50 baths. The result was good 18 months after the conclusion of the treatment. Dr. Horrocks remarked that the temperature of the bath should be raised slowly or blistering of the skin might result; also that the general condition of the patient should be carefully watched as a rise of the temperature of the blood and faintness might supervene.—Dr. R. H. Crowley made remarks on six cases of Pernicious Anæmia and showed a tabulated report of the examination of the blood in each case. In many cases the illness commenced suddenly, signs of gastro-intestinal irritation being frequently present. One of the patients was an apparently healthy farm-labourer who was seized with sudden pallor and shortness of breath. Under treatment he improved and was able to resume his work. A second attack came on and ended in temporary recovery. A third attack was accompanied by extensive dropsy and extreme weakness, but when the man seemed to be at the point of death he suddenly began to improve and in the end was discharged from hospital. In all cases there was diminution of the count of both red and white cells. The hæmoglobin percentage was not reduced proportionately to the reduction of the red cells. Diagnostic points were: (1) the presence of large nucleated red cells; and (2) a count of red cells as low as 1,000,000 per cubic millimetre with no proportionate increase of white cells. Owing to the frequent presence of gastro-intestinal symptoms the disease had been regarded by some as due to toxic absorption from the digestive tract, but there was not conclusive evidence of this. The empirical treatment with arsenic seemed sometimes to give favourable results, but owing to the sudden variations in the course of the disease it was exceedingly difficult to estimate the effect of any remedy.—Dr. H. J. Campbell alluded to a case in which an impending fatal termination was apparently averted by the administration of cannabis indica.—Dr. S. Johnston spoke of a case in which the inhalation of oxygen had been followed by temporary improvement, the patient dying from a relapse several weeks later.—Dr. J. B. Hall showed a patient from whom the Sigmoid Flexure and Upper Part of the Rectum had been Removed for Intussusception.—Other patients and specimens were shown by Dr. James Kerr, Dr. Mason, Dr. F. W. Eurich, Dr. Crowley, Dr. S. Lodge, jun., Mr. Ling, Mr. C. F. M. Althorp, Dr. B. H. Slater, and Dr. T. Jason Wood.

SOCIETY OF ANÆSTHETISTS.—A meeting of this society was held on Feb. 15th, Dr. J. F. W. Silk, the President, being in the chair.—The President explained that the meeting was held in lieu of the ordinary meeting on Feb. 1st, which had been postponed on account of the lamented death of Her Majesty the late Queen.—Mr. George Eastes then read his paper on the Conclusions of the Anæsthetics Committee of the British Medical Association.[1] In the discussion which followed Dr. C. Childs remarked that, although he had not taken any active part in the work of the committee for the last five years, he still maintained an interest in the subject and knew what a tremendous undertaking an investigation of the sort involved. He then gave a short account of the inception and formation of the committee and spoke in admiration of their self-denial and energy. He thought that their labours had been brought to a triumphant conclusion and that certain important questions had been very definitely answered.—Dr. Dudley Buxton pointed out that in his paper at Bournemouth, in consequence of which the committee had been originally appointed, he had insisted upon the importance of attacking the subject from the clinical side, and that it was with this object that the investigation had been commenced. He thought that similar investigations should be made in every hospital and public institution. Although much of the time spent upon the commission had been lost, this was inevitable, as they had to feel their way; nevertheless, the results arrived at were of great value, as giving definite evidence, supported by statistics, of certain facts which had hitherto been only matters of surmise or probability. A great feature of the report was the abstracts of the cases upon which the conclusions of the committee were based. He thought that in one or two points the conclusions required amplification and modification, as, for instance, in respect to imperfect or incomplete anæsthesia and with regard to the after occurrence of bronchitis.—The President regretted that such a comparatively small number of "mixtures" had come under the notice of the committee, and he did not think that the conclusions drawn from such small numbers could be looked upon as reliable. He thought, too, that it was a pity that greater stress had not been laid upon the importance of carefully selecting the anæsthetic in accordance with individual requirements, and he quite agreed with Dr. Buxton that inappropriate selection accounted for a good many of the cases of bronchitis.—Mr. Eastes replied.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on Feb. 27th, Dr. A. J. Harrison, the President, being in the chair.—Dr. P. S. Abraham showed a case of Lupus Erythematosus in a young woman, both cheeks and the backs of the finger being affected. When first seen the patches on the cheeks were vesicating.—Mr. G. Pernet called attention to the fact that there was a history of phthisis in the patient's family, as was so often found to be the case in lupus erythematosus.—Dr. Abraham also showed a case of Raynaud's Disease in a middle-aged woman affecting the tips of the fingers and the toes.—Dr. R. L. Bowles remarked that the patient's heart was large, probably dilated, and advised that treatment should be directed to improving the nervous system.—Mr. T. J. Hitchins said that, acting on the advice of Mr. Jonathan Hutchinson, he had treated a case of Raynaud's disease of nine years' duration which had been under his care with quinine and opium with very satisfactory results.—Mr. Pernet recommended nitro-glycerine in these cases.—The President showed (1) a Photograph of a Bromide Eruption which occurred in a single patch on the site of an old injury from a kick on the leg of a boy; and (2) a drawing of a Tertiary Syphilitic Eruption on the leg

[1] Brit. Med. Jour., Feb. 23rd, 1901.

of an old man.—Mr. Pernet showed several Microscopical Specimens.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—A meeting of the Section of Obstetrics was held on Feb. 8th, Dr. A. V. Macan, the President, being in the chair.—Dr. Alfred Smith showed Two Large Fibro-myomatous Uteri which he had removed for bladder symptoms. They were interesting from the fact that both tubes and ovaries were at the right side of the pelvis close to the brim. The displacement was caused by the growth of the fibro-myoma.—Dr. Alfred Smith also showed an Ovarian Cyst of the size of a six months' pregnant uterus which he had removed from a patient, aged 34 years. It had become more or less solidified by repeated hæmorrhages into its spaces. There was a history of repeated attacks of abdominal pain which was at first mistaken for peritonitis. Extensive fresh adhesions were present; there was no torsion of the pedicle and microscopic sections did not reveal any peculiarity of structure which would explain the presence of so large a defibrinated clot and the extensive fresh hæmorrhage into the centre of the cyst.—The President said it would be interesting to know what was the cause of the hæmorrhage in this case. One of the largest tumours which he had removed was a fibroid in which hæmorrhage had occurred, forming an enormous cyst. He thought that the attacks of pain which Dr. Smith had referred to were due to the hæmorrhage.

Reviews and Notices of Books.

Practical Gynæcology: a Comprehensive Text-book for Physicians and Students. By E. E. MONTGOMERY, M.D. With 527 Illustrations. London: Rebman, Limited. 1901. Royal 8vo. Pp. 819. Price 25*s.* net.

THE author of this work begins his preface by saying that he will offer no apology for presenting another text-book on gynæcology. We are inclined to think that the time has almost come when it should be incumbent upon all writers of such works to do so, unless they can produce evidence of some originality in the book they have written or some urgent need for its production. Dr. Montgomery might reply that his text-book is original in its method of classification. No doubt this is so, and possibly the method has all the advantages claimed for it. The whole subject is considered under four main divisions—viz., Malformations, Inflammations, Deviations, and Tumours. Such a classification leads to some misuse of terms; for instance, the inclusion of injuries to the cervix and rupture of the perineum amongst malformations. The first part of the book gives a good and full account of the various methods of examination of the patient, and the anatomy and physiology of the pelvic organs. The author enters into considerable detail on the matter of operative procedures, no less than 19 different methods of repairing the perineum being described. Similar detail is shown in the section upon fistulæ, which gives a clear and well-illustrated recital of the operations that may be performed for such conditions. This is one of the best parts of the book. In considering vaginismus no clear distinction is drawn between cases of true vaginismus and dyspareunia, and yet the difference is important from the point of view of treatment. Under urethritis Dr. Montgomery writes of simple hyperæmia, an acute urethritis, a chronic interstitial urethritis, and a follicular urethritis. He enters very fully into the important question of treating these conditions, which too often receive but scant notice in books upon diseases of women. We cannot agree with the statement that "chronic metritis is responsible for a large proportion of the sofa and bath-chair population—the nervous, debilitated, dyspeptic women who wander from physician to physician or crowd the watering-places during the summer." We would rather have said that the causes of chronic metritis are responsible, not the disease itself, which is a matter of much less importance than the reader would be led to believe from the long list of symptoms which Dr. Montgomery mentions as caused by its presence. Under the treatment of inflammatory conditions of the tubes due stress is laid upon the great importance of complete rest and local treatment before resorting to operative interference. The balance is duly held between the abdominal and vaginal methods of operation and the author points out how impossible it is and always will be to treat all cases by the same route. The advice is given to leave a piece of the ovary whenever possible, even if it be necessary to remove both tubes; and this is undoubtedly the right treatment in suitable cases. A good section is that dealing with displacements of the uterus. It is well written and the importance of the accompanying conditions is insisted upon. In the operative treatment of backward displacement Alexander's operation is not recommended. The medicinal treatment of fibroid tumours of the uterus receives more space than is usually allotted to it in the modern text-book, which only too often is mainly concerned with various methods of removing these tumours. We should like to know upon what authority the author makes the statement that a benign (*sic*) cystic mole can give rise to metastases. The book cannot, as we have hinted, lay claim to any great originality, nor can it be regarded as an authoritative work upon gynæcology. It contains, however, a considerable amount of useful information and is well illustrated by a large number of good and well-reproduced drawings. It is surprising to find such errors as "Kuster" for Küstner, "Wydal" for Wyder, "Gärtner" for Gartner, "Pruritis," "Ascarus Scabii" for Acarus Scabiei, and statements such as that on page 553, where, speaking of the microscopic appearance of fibro-myomata of the uterus, the author says: "Occasionally between the muscle bundles are spores—lymph glands lined with endothelium."

Medical Monograph Series. Edited by DAVID WALSH, M.D. Edin. No. 1. Contagious Ophthalmia, Acute and Chronic. By SYDNEY STEPHENSON, Ophthalmic Surgeon to the Evelina Hospital and to the North-Eastern Hospital for Children. London: Baillière, Tindall, and Cox. 1900. Pp. 84. Price 2*s.* 6*d.* net.

THIS little work, which ought to have been noticed at an earlier date, is the first of a series of monographs intended to give to students and practitioners the best and most recent information on important subjects. Contagious ophthalmia is certainly one of these, and that affection could not have been entrusted to better hands than those of Mr. Sydney Stephenson, who has had quite exceptional opportunities of witnessing its outbreak, of seeing its results, and of devising means for preventing its spread in large schools. Mr. Stephenson points out that this particular disease accounts for 10 per cent. of all cases of blindness and yet is one of those that if early recognised and properly treated may be regarded as curable without the slightest impairment of vision; and, indeed, when the circumstances that lead to its occurrence are thoroughly appreciated it may, by the adoption of judicious measures, be almost invariably prevented. In describing the various forms of the disease grouped under the term "contagious ophthalmia" Mr. Stephenson distinguishes three parts of the conjunctiva—the palpebral and ocular regions and the retrotarsal folds—and gives directions for exposing the superior fold. A retractor, he remarks, is hardly requisite, since anybody possessed of a moderate amount of manual skill can bring it into view. He gives a woodcut of the retractor which, if really required, he uses, but it is badly shaded and looks as if it had a button at the end. Recently-ulcerated spots of the cornea and parts of that membrane where the epithelium is degenerated are stained a bright green colour, and the formula given is a useful one; it is,

fluorescin two parts, sodium carbonate three and a half parts, and distilled water 100 parts. Mr. Stephenson insists on the necessity for thorough asepsis, both on the part of the surgeon and of his instruments, and also that goggles should be worn whilst injections are used, and, further, that the tear passages should in all instances be carefully examined and cleansed. Bacteriological examination of the discharge is of great importance and utility. Full accounts are given of the methods of examination both by means of cover-glass preparations and by cultures. The basic stains recommended are methylene blue, carbol-fuchsin, and thionine blue, gentian, or methyl violet. A second cover-glass should always be treated by Gram's method. A plate is given showing some of the organisms met with. Mr. Stephenson considers that mucopurulent ophthalmia, purulent ophthalmia, granular ophthalmia, and membranous ophthalmia are all separate and distinct affections and have a different etiology, though doubtless they possess certain features in common. In regard to the frequency of gonorrhœal conjunctivitis in ophthalmia neonatorum it appears that amongst 446 cases of ophthalmia neonatorum gonococci were present in 72·83 per cent. The conditions known as granular ophthalmia and membranous, croupous, and diphtherial conjunctivitis are all described with much precision. The work, though small, contains a great deal of information and will be found very useful by the practitioner.

A Contribution to the Study of the Blood and Blood-pressure. By GEORGE OLIVER, M.D., F.R.C.P. Lond. London: H. K. Lewis. 8vo, pp. 276. Price 7*s.* 6*d.*

WE should like to see more works of this kind issue from the pens of other physiologists. The author tells us that the leisure afforded by the winters of the past 10 years has enabled him to study in an experimental way several physiological questions having a bearing on clinical medicine, and his professional life during the summer months has furnished opportunities of testing the physiological positions suggested by these inquiries and the practical efficiency of the instrumental methods of observation employed. This is precisely the method in which both physiology and medicine should be studied, and if it were systematically carried out each of these pursuits would be the gainer. The very first chapter shows that as soon as precise experiments are instituted unsuspected difficulties arise. In endeavouring to obtain standard colour tests it was found that no one substance or combination of substances in solution can correctly furnish a percentage series of gradations of hæmoglobin. Such a substance, for example, as carmine, which in dilute solution exactly corresponds with a definite proportion of hæmoglobin, does not present when dissolved in larger proportion precisely the same tint as a corresponding concentration of hæmoglobin.

Dr. Oliver has found Mr. Lovibond's system of graded glasses the best means of determining and comparing variations and degrees of colour. He takes as his standard the mean percentage of hæmoglobin present in healthy human blood containing 5,000,000 corpuscles per cubic millimetre. This amounts to 15·5 per cent. of hæmoglobin and is represented by 100 degrees, and each degree of the scale is equivalent to 0·155 per cent. of oxyhæmoglobin in the sample of blood under examination. Thus 100 degrees represent 15·5 per cent. of hæmoglobin, and determinations above or below that point require the addition or subtraction of 0·155 per cent. for each degree. The examination of the colour of the blood is best conducted by candlelight, daylight being too variable. The author gives a full description of the construction and mode of using his hæmoglobinometer and hæmocytometer. Amongst the many interesting results which Dr. Oliver obtained from his experiments the following may be mentioned. The blood furnished by different regions of the body does not always afford the same proportions of corpuscles and hæmoglobin. The blood furnished by the toes, for example, is much poorer than that afforded by the fingers, but after the application of massage no appreciable difference was observable. Gravity exerts considerable influence, so that the proportion of hæmoglobin is remarkably reduced in the toes and fingers by the *passive* elevation of the hand or foot for some minutes, but if the elevation be the result of muscular effort no diminution is observed. Local muscular action, however induced, causes an immediate, decisive, and proportionate rise in the corpuscles and in the hæmoglobin. Two series of 800 night and morning observations made at bed-time and on rising demonstrated that in the subjects of the experiments the daily work of the waking hours produces a fall in the hæmoglobin value of the corpuscles, and proved that rest and sleep not merely restore the hæmoglobin lost during the working portion of the day, but provide a slight excess beyond it. There is a fall in the chromocytes and hæmoglobin during digestion. Removal from the sea-level to altitudes of several thousand feet is rapidly followed by increase in the number of the red corpuscles, but descent to plains again is equally quickly followed by a diminution in their number. The author discusses at some length the possibilities and extent of error that may lie in these statements. Hot baths lower the percentage of the corpuscles; cold baths raise it. The latter part of the book is chiefly occupied with the consideration of blood-pressure and the circumstances which modify it. Dr. Oliver has devised a hæmodynamometer, with a pad containing fluid, of convenient size, by means of which the blood-pressure in the arteries and veins can be determined with much accuracy, and he has made a large number of observations in healthy subjects on the effects on the blood-pressure of various physiological conditions. Many of the sections have a direct clinical bearing, and we recommend this interesting and very original treatise to the notice of every thoughtful physician.

Maladies du Pharynx: Traité Médico-chirurgical. Par E. ESCAT. Préface par LUBET-BARBON. Paris: Carré et Naud. 1901. Pp. 586. With 150 Illustrations. Price 16 fr.

THIS is a very lengthy work, but notwithstanding this fact a careful study of Dr. Escat's work will certainly repay anyone who is sufficiently interested in the subject to commence it; after that there is no great temptation to put the book aside, for the style is easy and from an English point of view particularly readable. The author has given us a really admirable history of the present knowledge of the diseases of the pharynx and their treatment, but his knowledge of British contemporary work is scanty. Thus the admirable researches of Kelly on pharyngo-mycosis and of Paterson on the fossa triangularis, which may be given as casual examples of omission, are not mentioned. On the vexed question as to whether there is such a condition as rheumatic tonsillitis Dr. Escat exercises a nice discrimination and concludes with a summary of the views of Charrin, that there is no specific rheumatic microbe, but that any pathogenic organism may cause it; that the passage in the blood-stream of such microbes will not alone produce rheumatism, but needs the "acid dyscrasia" to develop rheumatism. The description of the ulcéro-membraneuse angine or angine diphthéroïde de Vincent is particularly useful. Vincent's original work was not noticed by workers in this country, so that we are glad to see prominence again given to it by Dr. Escat.

Although, speaking generally, the various diseases of the pharynx are well classified and described, occasionally the author errs on the side of subdivision. To subdivide, for example, quinsies according as to whether the pus forms anteriorly or posteriorly to the tonsil is to be too precise,

and when it is found that each of the tonsils requires a special detailed description for attacks of the same nature we doubt whether any useful purpose is served by such an arrangement of material.

Amongst the more interesting chapters are those dwelling on the vesicular affections of the pharynx; tumours of the base of the tongue are not so ably treated and there is one chapter that will, we hope, obtain less prominence in any future edition, that on varices of the base of the tongue. Like too many observers Dr. Escat looks upon hypertrophy of the lingual tonsil from the point of view that the condition is the disease, whereas it is a local manifestation of a more general disturbance.

The pen-and-ink sketches are admirable and are mostly by the author. The book will certainly be valuable for reference and should find a place upon the shelves of most medical libraries.

LIBRARY TABLE.

Atlas and Epitome of Gynæcology. By Dr. OSKAR SCHAEFFER. Authorised translation from the second revised and enlarged German edition. Edited by RICHARD C. NORRIS, A.M., M.D. With 207 Coloured Illustrations on 90 Plates and 62 Illustrations in the text. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 272. 8vo. Price 15*s.* net.—A notice of the second German edition of this book has already appeared in THE LANCET of Oct. 28th, 1899. The present edition is edited by Dr. Richard C. Norris and the translation has been carried out by Dr. Hersey Thomas. It is unnecessary for us to reiterate our opinion of the work. According to the editor's preface it may be considered to occupy a position midway between the *quiz compend* and the more pretentious works on gynæcology. The coloured plates and illustrations are of value and many of them very good. They will, no doubt, be of service to those students who are unable to attend a proper clinic and for use in class demonstrations. Possibly in its English form the book may appeal to a certain number of American or English students. The translator has done his work well and the book contains a large amount of information although not in a very readable form. In these days of advanced gynæcology it is interesting to note that the editor remarks: "The paragraphs devoted to the treatment of various diseases are very conservative, in some instances perhaps too much so for the aggressive surgeon."

Atlas der Nasenkrankheiten. Enthaltend 356 Figuren in 475 Einzelbildern auf 38 Tafeln. (*Atlas of Diseases of the Nose.* Containing 356 Figures of 475 separate drawings in 38 Plates.) Von Hofrath Dr. R. KRIEG. Stuttgart: F. Enke. Glasgow: F. Bauermeister. Parts 3 and 4. Price 6 marks each.—The morbid conditions dealt with in these parts of this excellent atlas, in 10 plates, are: fractures and luxations; hæmatomas and abscess of the septum; atresia and synechiæ; acute, diphtheritic, fibrinous chronic, and hypertrophic rhinitis; polypi, posterior choanal polypi, and polypoid hypertrophies; septal hypertrophies; atrophic rhinitis and rhinitis sicca. The colouring of these plates does not show the fault that was referred to in the notice that was given of the former two; it is most faithful to nature or should we say to life? The careful notes on which the text must have been based seem to exemplify the unwieldy proportions to which our own hospital out-patient departments have grown, for it would be extremely difficult for anyone to find the necessary time to compile such notes in a London clinic. The term "rhinitis sicca" is one too much neglected in books on nasal diseases, as is also the word "operculum" for the anterior extremity of the middle turbinate, both expressions being freely used by Dr. Krieg. Papillary hypertrophy of the turbinates, a point investigated by Wingrave who considers that the condition is incorrectly termed papillary, is nevertheless one which conveys an extremely correct impression of the morbid state, and the illustrations of it given by Dr. Krieg are most instructive. In only one respect are we inclined to find fault with the draughtsmanship and that is in the representation of the cushion of the Eustachian tube, a minor point.

Die Krankheiten der Frauen. (*Diseases of Women.*) By Professor HEINRICH FRITSCH. Ninth revised edition. With 271 Illustrations. Braunschweig: Friedrich Wreden. 1900. Pp. 650. 8vo.—No lengthy notice is required on our part of such a well-known work as Professor Fritsch's Text-book on Gynæcology which has recently appeared in a ninth edition. The new edition contains two new chapters. The first is devoted to Gynæcological Antisepsis and contains a very complete account of the origin and causes of wound infection, its results, its prevention, and the best method of attaining antisepsis and asepsis. For the hands Professor Fritsch recommends prolonged scrubbing with soft soap and water, scrubbing in alcohol, and finally in a 1 in 1000 solution of perchloride of mercury. He also directs that the operator is to brush his hair with a brush dipped in the sublimate solution and is to do the same thing to his beard. The nose is to be washed over and the nostrils swabbed out with the solution and an antiseptic mouth-wash of eucalyptol or some similar substance used. After such a preparation an operator should certainly be in a condition of surgical cleanliness. The use of indiarubber or cotton gloves the author does not approve. The second new chapter is devoted to the After-treatment of Cases of Laparotomy. It deals with the best methods of suturing the abdominal wound, the dressing of the wounds, the after-treatment of the patients, the various complications that may arise, and the commonest causes of death after an abdominal section. The question of the treatment of ileus and the various complications of the operation itself, such as adhesions or the formation of fistulous communications with various viscera, is gone into and their treatment discussed. The book bears evidence of careful revision and all the approved modern methods are noticed, such as the use of steam in the uterus after curettage. A large number of new illustrations have been added, and the book well sustains its reputation as one of the best of the smaller German text-books of gynæcology.

A Text-book of Obstetrics. By BARTON COOKE HIRST, M.D. With 653 Illustrations. Second edition. London and Philadelphia: W. B. Saunders and Co. 1900. 8vo. Pp. 846. Price 21*s.* net.—In our notice of the first edition of this book in THE LANCET of May 13th, 1899, we pointed out that Professor Hirst had written a very good text-book of obstetrics. The fact that it has so soon been found necessary to issue a second edition shows that our opinion has been shared by others. The second edition, which has just appeared is in reality rather a reprint than another edition. No extensive alterations have been made and no revision has been attempted. It is a pity that this has not been done, since the first edition showed certain omissions and contained certain statements to which we called attention and which might well have been corrected or modified. There can be no doubt, however, but that the present issue of this work will meet with as much favour as the last.

How to Keep "Fit"; or the Soldier's Guide to Health in Field, Camp, and Quarters. Compiled by Surgeon-Captain H. WAITE, V.M.S. Aldershot: Gale and Polden, Limited. Price 3*d.* Pp. 40.—This is a very little book of 40 pages, measuring four inches by two and three-quarter inches, but all the same it is a most excellent work, full of practical and simple hints. We are not sure of the advisability of passing a needleful of worsted through a blister and leaving the worsted in (p. 27), but think it better merely to snip the

blister with a clean pair of scissors or open it with a clean knife. Of course, if Surgeon-Captain Waite means that the worsted should only be left in when the patient is not marching his advice is all right, but this point is not made plain. This is the only carping criticism we have to make. We congratulate Surgeon-Captain Waite on supplying the soldier with portable rules of conduct in many cases of surgical and medical trouble that may arise when he is far from expert assistance.

JOURNALS AND MAGAZINES.

La Cirugía Contemporánea.—Mexico is well known to have made rapid strides in various departments under its present esteemed ruler. Amongst other matters its medical literature is growing both in quality and in quantity. For the last three years a Mexican Surgical Society has been in existence and this has now commenced to publish a monthly organ entitled *La Cirugía Contemporánea*, under the editorial charge of Dr. Ramón Macías. The first number, that for Jan. 15th, 1901, contains articles on the Induction of Anæsthesia for Pelvic Operations by the Intra-rachidian and Intra-arachnoid Injection of Cocaine in the Lumbar Region, by Dr. Villarreal, and on a case of Complete Abdominal Hysterectomy for an Enormous Uterine Fibroid, by Dr. Armendariz.

The Cornhill Magazine for March opens with a paper by Mr. C. H. Firth on the treatment of the sick and wounded in the Great Civil War in this country in the seventeenth century, derived largely from unpublished documents. Mr. Firth tells a curious story of a medical man in the army of the seventeenth century who had been impeached for incompetence and neglect. He replied by forwarding a statement favourable to himself which had been signed by grateful survivors, while he pointed out that those who died had died by the Divine will. "What," he pleaded, "is the physician or surgeon but Dame Nature's handiman to be aiding and assisting to her. But the Great God of Heaven has ordained and appointed severall diseases which are incident to men, and they have to attend them one Death, who does and will prevail, notwithstanding the most excellent means which the gravest or wisest physician or surgeon can use in the world, and this we may see by daily experience." The whole article is worth reading. And so is a paper by Mr. Basil Williams, late a gunner in the C.I.V. Battery, founded upon a bundle of Boer war bulletins. These documents mostly consisted of copies of the official telegrams sent to Bethlehem during the earlier days of the war, and show the Boers to have been quite well informed.

ASYLUM REPORTS.

London County Asylum, Horton (Report for the year ending May 7th, 1900).—The asylum was formally opened by Mr. Hubbard, chairman of the London County Asylums Committee, on June 3rd, 1899. Patients were first admitted on June 7th into the three wards which were then ready for their reception. By Oct. 2nd all the wards in succession had been completed and opened. The average number of patients resident during the 11 months covered by the report was 414 and comprised 67 males and 347 females. The total number admitted was 782. Of these 671 were transfers from other asylums. Dr. Frederick Bryan, the medical superintendent, states in his report that "in only 2 per cent. of the transfers was there any probability of recovery," while the proportion of patients with wet and dirty habits was one in five of the total number admitted. The nucleus of the female nursing staff was drawn by permission from the London County Asylums at Colney Hatch, Claybury, Cane-hill, and Banstead. Though built mainly for female patients the Asylums Committee have allowed buildings and accommodation for 110 working male patients. Amongst this class 50 epileptic patients are included, who have been received from the sister asylums of the County of London and are destined for the future "epileptic colony." The conditions at Horton are said to be as nearly akin to those at an epileptic colony as possible and the results are thus far described as quite satisfactory. There has been no serious accident or inquest during the year. One male patient escaped but returned of his own accord the next day. A fire-brigade has been organised and is composed of female attendants, supplemented by two male attendants to work the outside hydrants. "Numerous drills have been held and the brigade is in a satisfactory condition." The health of the institution was uniformly good until the onset of winter when influenza broke out and caused much illness. During February and March, 1900, there occurred many cases of sore-throat, chiefly among the staff, and a number of cases of diarrhœa among both patients and staff. There were also several cases of ulcerative colitis. Nine patients, all females, were discharged during the year as recovered. The deaths amounted to eight, and of these one each was due to epilepsy, cerebral hæmorrhage, peritonitis, renal disease, and phthisis, while three were due to pneumonia. The heating arrangements applied to the asylum worked so well that there was no practical difficulty in raising the temperature to any required degree in the coldest weather. Open fires have been used in all the wards for the sake of ventilation and cheerfulness, and for this purpose the wood on the estate, of which there is an ample quantity, has been chiefly used. The whole of the milk-supply is produced on the estate. There being no bakery bread is obtained by contract *pro tem.* The expenditure for the year for additions, alterations, and repairs amounted to £2812. The Lunacy Commissioners in their report state that the medical case-books, which are prepared on elaborate principles, are very carefully kept.

New Inventions.

BENSON'S JACKETED ICE-BOWL.

WE have received from Messrs. W. A. S. Benson and Co. of Bond-street, a specimen of their jacketed ice-bowl. The illustration shows the appearance of the bowl. The principle upon which it is constructed is that of isolating the interior from the outside air by means of an air jacket. Everyone knows how difficult it is to keep a small supply of broken ice from melting, but from an experiment which we made with this bowl we should say it would prove very useful for the sick room. A small quantity of broken-up

ice was placed in a handkerchief and weighed. The ice and the handkerchief together weighed just over half a pound. The ice and the handkerchief were then placed in the bowl at 9.30 A.M. on Feb. 25th, which was by no means a cold day. The bowl was kept in a dining-room with a fire, the temperature of the room being about 60° F., until 7.30 P.M., when the handkerchief and the remaining ice were again weighed. The loss in weight was just one half—i.e., the handkerchief and ice together weighed one quarter of a pound. The bowl will hold 2 lb. of ice when full and we think it should prove a valuable addition to invalid furniture.

THE LANCET.

LONDON: SATURDAY, MARCH 9, 1901.

Uncertified Deaths.

IT is satisfactory to find that one of the first deputations received by the new President of the Local Government Board consisted of members of the General Medical Council who were appointed to bring under his notice the dangerous state of the law regulating the registration of deaths in cases where there has been no regular medical attendance. The interview was not a public one, but we have every reason for believing that it was satisfactory to the deputation. Mr. LONG has shown himself, in one conspicuous instance, capable of appreciating the gravity that is implied in the occurrence of a largely increased number of deaths from a rare disease; and, what is more, he showed himself capable of the courage to incur temporary abuse and unpopularity in persistent and finally effectual efforts for the prevention of this disease. This is the kind of man to whom the profession and the public may look with some hope for an effort to improve the law guiding registrars in regard to the registration of cases of death where there has been no medical attendance and where no medical certificate is obtainable. The number of such deaths, we need not say, greatly exceeds the number of deaths from hydrophobia and they constitute little short of a scandal in a civilised community where medical help abounds. The whole subject has been well elucidated by the report of the Committee of 1893, of which Sir WALTER FOSTER was the president. We have no intention of going over the evidence adduced before this Committee or even of summarising its principal conclusions. Our object rather is to urge the President of the Local Government Board to legislate on this subject. Such deaths represent carelessness, neglect, want of intelligence, and a deficient respect for human life. They occur mostly in children and in persons advanced in life—classes eminently entitled to the consideration of the legislature. If the present state of the law is not answerable for these deaths it distinctly favours their occurrence by its laxness. It is of no use to blame individual registrars, for undoubtedly the law permits them a certain discretion in the registration of deaths. The General Medical Council in bringing this subject under the notice of the Government is only doing its duty. For years past, through its late President, Sir RICHARD QUAIN, and more lately through Sir WILLIAM TURNER, it has been making representations to different departments of Government with a view to legislation. It has been moved to do so by representations from all parts of the country and even by communications from the Home Office, showing the extent to which deaths are registered on the loosest information, supplied by druggists and unqualified practitioners of all sorts.

The Home Office has lately done good service in directing public attention to one branch of this subject which requires special attention—viz., the unsatisfactory way in which coroners and juries report the result of their inquiries. According to the last published annual report of the Registrar-General, that for 1898, there were in England and Wales 34,000 inquests, but only in comparatively few of these cases is any information given in the verdicts as to the actual cause of death. The Registrar-General complains that the verdicts of coroners' juries are frequently so worded as to obscure the medical evidence given at the inquest concerning the cause of death, and, of course, as we know too well, at many inquests no medical evidence is sought at all. We take this opportunity of publishing an extract, given by the Registrar-General in his report for 1898, from a report of a departmental committee of the Home Office on this point:—"We are so much impressed by the insufficiency and untrustworthiness of the statistics relating to particular causes of mortality which can be gathered from returns of coroners' verdicts that we venture ..... to recommend strongly that some steps should be taken to secure that their verdicts shall lend themselves more readily to clear classification by the Registrar-General."

When we remember that about 6 per cent. of deaths are certified by coroners the importance of this recommendation will be apparent. In Liverpool alone 1021 deaths out of 16,861 in 1899 were the subject of a coroner's investigation. All coroners are not alike careless of the value of their verdicts as sources of information to the Registrar-General. We are glad to know that London coroners are credited with wording verdicts in such terms as to give them some of the value of medical certificates. Even without any change of the law all coroners can do the same when medical evidence is in their hands. We venture to appeal to them to do so, and doubtless in any case the subject will have the attention of the President of the Local Government Board. The great statistical records of the nation, over which we spend so much money, are impaired in their value by the carelessness of coroners. Surely it is little for the country to expect from them that their investigations shall be careful and minute and that their account of a death shall include wherever possible a statement of its cause. We congratulate the General Medical Council on its vigilance in this matter, which we trust will be continued till a much needed amendment of the law is obtained. And amendment should aim at two great points: firstly, to secure that all seriously sick persons shall have such medical attendance as will justify medical certification of the cause of death; and, secondly, failing this, that information of the cause of death, properly and clearly worded, shall be forthcoming from the coroner.

Trials for Murder at the Old Bailey.

DURING the course of last week three persons indicted for wilful murder were tried at the Central Criminal Court. One was acquitted and the others were convicted and sentenced to death. All the cases presented points of medical interest.

The most sensational case was that in which HERBERT

JOHN BENNETT, aged 21 years, was charged with having murdered his wife, 23 years of age, on the beach at Yarmouth on Sept. 22nd, 1900. A writ of certiorari had been issued directing that the trial should take place in London instead of Norwich owing to the strong local feeling that had been evinced against the prisoner. The evidence against the accused was circumstantial, but it was of such cogency as to warrant but one interpretation. BENNETT and his wife, who were married in 1897, had lived at different places and under different names. About July 12th, 1900, Mrs. BENNETT took 1, Glencoe-villas, Bexley Heath, and remained there till Sept. 15th, when she went with her little girl to Yarmouth under the assumed name of HOOD. Her husband during this period was living as a single man at Woolwich, where he was employed at the Arsenal. On the night of Sept. 22nd a man and a woman were observed by two people on the beach at Yarmouth and a cry of "Mercy, mercy," and subsequently groans were heard. Early the following morning the dead body of a woman was discovered. Round her neck a mohair bootlace was tightly tied and this had killed her by strangulation. A coroner's inquisition was held and adjourned to Oct. 29th, when the jury returned an open verdict as the woman could not be identified. On the evening of Sept. 22nd Mrs. BENNETT received a letter bearing the Woolwich postmark. Her clothes had on them the laundry mark "599." These were the clues that eventually led to the elucidation of the mystery. On March 7th, 1900, BENNETT booked passages for Cape Town in the names of "Mr. and Mrs. HOOD." After staying four days at the Cape they returned to England. In the house at Glencoe-villas some articles of clothing were found bearing the mark "599." In Mrs. BENNETT'S possession was a key which unlocked the door of the house. In the summer of 1900 the prisoner became acquainted and eventually engaged to a girl named ALICE MEADOWS who believed that he was a single man. He endeavoured to obtain rooms for himself and her at the house in which his wife afterwards stayed at Yarmouth, but failing to get accommodation he took her to the Crown and Anchor Hotel, where they occupied separate rooms. When arrested BENNETT said, "I have never been to Yarmouth, I have not lived with my wife since January"—a palpable falsehood. A photograph of Mrs. BENNETT and her child which had been taken at Yarmouth showed a watch-chain. Neither this nor a watch were found upon her body or at her rooms; but in BENNETT'S lodgings at Woolwich a chain and a watch which were proved to have belonged to the deceased were discovered after his arrest. It was alleged by the prosecution that the accused took his wife to Yarmouth on Sept. 15th, left her there without going to her intended residence, and returned to Woolwich. As proof that he could not have been at Yarmouth on the day of the murder, Sept. 22nd, he referred the police to the evidence that two fellow-workmen could give, but these persons did not endorse his statement. For the defence an *alibi* was set up. A witness testified that on the evening of Sept. 22nd he was in BENNETT'S company for an hour, but this evidence, instead of being disclosed at an early date, was only brought forward towards the end of the trial. Without questioning the *bona fides* of the witness he may have mistaken the identity of BENNETT and also the date. Moreover, there was absolutely no corroboration, and the accused, who was absent from his lodgings on the night of Sept. 22nd, had not himself referred to the alleged incident. A prisoner on trial for murder is an admissible witness in his defence. His declining to go into the box is not considered to weigh against him, yet in most cases an innocent man would gladly avail himself of the opportunity, and this BENNETT failed to do. As regards the motive for the deed there was abundant evidence. The criminal had treated his wife cruelly and had once been heard to threaten her life. He was living apart from her though near to her, and that without any assigned adequate reason in so far as her conduct was concerned. He was leading a life of misrepresentation, and he had contracted an engagement with another woman who was ignorant of his guilt. His past was one of moral laxity; his present is that of a cold, cruel, convicted murderer.

Of another type of the criminal homicide was GEORGE HENRY PARKER, *alias* HILL, who was arraigned before Mr. Justice PHILLIMORE for having killed Mr. WILLIAM PEARSON in a railway carriage on the South-Western Railway on Jan. 18th, 1901. The evidence in this case was direct or personal, not circumstantial as that which secured the conviction of BENNETT. The deed was done in the presence of a third traveller who was seriously wounded at the same time either accidentally or intentionally. The accused man, aged 23 years, had apparently led a wild, dissolute life. On the day of the murder he took a ticket from Portsmouth to Winchester. At the latter station Mr. PEARSON, who was previously unknown to the prisoner, got into the train. After reading a paper he fell asleep. Soon after passing Surbiton PARKER without any warning shot Mr. PEARSON in the head, and immediately began to rifle his pockets. He threw the revolver out of the train, and on arriving at Vauxhall left the carriage whilst it was in motion and made a determined effort to escape. A Mrs. KING, the witness of the tragedy, raised an alarm, and PARKER, after an exciting chase, was caught. After the murder of Mr. PEARSON he offered Mrs. KING a sovereign, part of the money rifled from the dead man's pocket. Whether he had bought the revolver with the intent of committing murder is doubtful. For some days prior to Jan. 18th he had been drinking heavily, and it may be that he found the instrument a ready agent to carry out an impulsive homicidal act. He was known to be without money, and the "getting some of his own back," as he expressed it, seems to have been the only motive for his act. Whilst in prison he made no attempt to extenuate his guilt, but wrote piteous letters to his father, to the widow of his victim, and to the woman with whom he had been staying at Portsmouth. His counsel argued that "love and drink had driven the prisoner mad." PARKER was convicted and sentenced to death, the judge holding out no hope of mercy.

MAUD EDDINGTON was indicted for the murder of her sweetheart, JOHN BELLIS, at 94, Fleet-road, Hampstead, on Jan. 14th, 1901. The coroner's jury who inquired into the death of BELLIS returned a verdict to the effect that the prisoner intended to commit suicide and that in a struggle

for the possession of the revolver the deceased was accidentally shot. Subsequently to this finding further evidence was forthcoming. The charge at the police court was continued and the prisoner was committed for trial. The evidence, partly confirmed by the statement of the accused, showed that she had felt some resentment against the relatives of the deceased, with whom he lived, for having, as she believed, slighted her and tried to cause an estrangement between her and her *fiancé*, and that this resentment had later been extended to him. The scene of the tragedy was a small closely packed oil and colour shop. On the afternoon of Jan. 14th a tramcar conductor heard the sound of shots. Upon going into the shop he found the deceased in a crouching position, insensible, and bleeding from wounds in the head. In one hand was a string which held some brushes together. A similar bundle had evidently dropped from the other hand. EDDINGTON was lying at full length on the floor with her head towards the door. Between the two stood some steps. At the far end of the counter beyond the man was some blood which had apparently fallen on the floor. Some five feet or so distant, and close to the right of the deceased, was a quantity of blood that had run down from his head. The deceased had two bullet-wounds, one of which passed obliquely downwards from left to right through the upper lip, the other one and a half inches behind the left ear. The shot which had caused the latter had gone through the lateral sinus and lodged against the opposite side of the skull. The prisoner had a graze and some small blisters on the right side of her forehead. Deceased did not regain consciousness before he died six and a half hours after the injury. The prisoner said that she had written a letter to deceased telling him of her intention to shoot herself in his presence. This letter was not discovered, but an envelope in her handwriting and bearing the date she named was found in a locked box belonging to the deceased. A letter which had been written by her at her home she had torn up and thrown into the fireplace. In it were the words "he shall lose everything." The prosecution relied on this as proving malice, but for the defence it was contended that the letter was torn up because it did not truly represent the feelings and ideas of the accused woman. The facts and suggestions put before the jury in seeking for a conviction on the capital charge were: (1) a motive of revenge for neglect and unrequited love; (2) the statement in the letter before referred to; (3) that the steps stood between the two persons; (4) that the clothes of the accused were not disarranged and that there was no blood upon them; (5) that the objects of merchandise in close proximity had not been disturbed; (6) that the man was holding in his fingers the string which tied the brushes together; and (7) that the two patches of blood were some distance apart, with no intervening marks. Lord COLERIDGE for the defence contended that the man was accidentally shot whilst endeavouring to wrest the revolver from her, and the prisoner swore that BELLIS seized the weapon in his left hand and it went off in the struggle. The jury adopted this view and acquitted the prisoner, who pleaded guilty to the further indictment of having fired with intent to kill herself. The judge for this offence sentenced her to 15 months' hard labour, remarking that by her wicked and foolish act she had sacrificed the life of the deceased who had by a praiseworthy act—according to the previous finding of the jury—tried to save her life.

Glasgow's Predicament.

GLASGOW is at present the *corpus vile* on which is being performed an experiment which if interesting to the onlooker is serious to the city. In the spring of last year small-pox was introduced through the port by a sailor whose case proved fatal. Since then the disease has lingered on persistently, no month being entirely free from it, though in one fortnight in August the notifications, which had been about 100 for the month of June, were reduced to three. In November there was another lull, but for December the cases numbered over 70, and, after the new year holidays had had time to show their influence in the way of infection conveyed by crowds moving about all through the city and collecting in places of amusement, the notifications increased to 350 in a fortnight. Since then they have considerably diminished, so that in two weeks in February they were down to 157, though again some increment is reported.

The experiment to which we refer is that of voluntary revaccination. Primary vaccination in Glasgow is well attended to, so far as numbers are concerned, but, in the absence of all official supervision such as exists everywhere in England, there is grave reason to fear that one-mark and two-mark vaccination is much commoner than it ought to be, and that the area even of the one or two marks is not such as would be considered satisfactory south of the Cheviots. In these circumstances revaccination is being advocated by the corporation and its medical officers, and every medical man who cares to undertake the duty is being remunerated for all operations performed on behalf of the sanitary authority. The results are noteworthy. When the offer was first made the people were lukewarm. They did not realise the dangers of small-pox and few took the trouble to protect themselves. Then increase of small-pox was followed by increase of vaccination, so that now it is said that in a population of some 700,000 about 300,000 have been recently revaccinated. Adding to these the children who do not require revaccination—for even poor vaccinations give an appreciable period of protection—there is now only a minority of the inhabitants liable to attack or death by variola. Yet the disease continues to linger on among this minority, and such is the general indifference that every lull in the attack-rate is followed by a lull in the revaccination-rate. It is obvious from these facts that Glasgow has no rooted objection to vaccination. The question is merely one of sufficiency or insufficiency of stimulus. Meanwhile, the epidemic drags on among those who have neglected to protect themselves, and the town council is at its wit's end how to stem the pestilence before it ruins the exhibition, which is to be formally opened by Royalty early in May. This condition of mind gives just the kind of opportunity required for the advocacy of all kinds of alleged remedies. Even the so-called Leicester system, which was dealt with at length in THE LANCET

several years ago,[1] and which proved so terrible a failure in unvaccinated Gloucester, is being trotted out as applicable to the case of Glasgow. Glasgow's plight may be bad enough, but we hardly think that, in an attempt to manage small-pox without vaccination, it is prepared to empty its scarlet fever wards and to distribute scarlet fever all through the community as Leicester did, or to risk such an extraordinary prevalence of that disease as Leicester experienced in its wild efforts to deal with small-pox. And as to revaccination, few lessons are more striking than that which Leicester has to offer Glasgow in respect of the behaviour of small-pox to its hospital staff. Of 40 nurses and attendants at the Leicester hospital six were foolish enough to refuse revaccination when small-pox broke out, and the enlightened borough council had too much respect for the liberty of the subject to think of exercising pressure on its municipal servants. Of these six members of the hospital staff only one needs any protection against small-pox to-day. Five of the six were attacked by the disease and one of the five died. The fact that Glasgow is most keenly anxious to stamp out small-pox in time to save its exhibition need not have the result of making it either badger its officials or lose its own head as to the preventive measures to adopt. There is one measure, and one only, which is capable of dealing with the present emergency. That measure is revaccination. Already a large part of the population is perfectly safe against small-pox. Those who have been successfully vaccinated under the offer of free vaccination, or privately, need have no fear whatever of the disease. They can go where they please and do what they please so far as small-pox is concerned. It is not in their hands that the saving of the situation lies. If the unvaccinated minority wish to protect themselves against small-pox and to prevent the forthcoming exhibition from ending in disastrous failure they can do so at once by accepting the protection which is offered to them. We are glad to learn that an additional staff of vaccinators is being appointed and that the offer is to be pressed home by house-to-house visitation. This should be done systematically and thoroughly. Every vaccinator should have his area mapped out for him and he should not merely make a single call at every house, but should call again and again, if necessary, till he has seen every individual and pointed out the personal responsibility which lies on everyone to take care that he at least shall make himself insusceptible to variolous infection. The town council should make perfectly certain that the staff appointed is amply sufficient, not only to do this work, but to do the whole of it in the course of a single week. If it does so, and if the people rise to a true sense of their individual responsibility in the matter, then we have no hesitation in definitely promising that by about the beginning of April the Glasgow small-pox epidemic will be a matter of history.
